CONTENTS

14 **Introduction** / Mario Ubilla, Horacio Torrent

16 **Modern Futures: Sustainable Development and Cultural Diversity** / Horacio Torrent

20 **MODERN FUTURES**

22 **The Role of Technologies in the Modern Movement and in the Future of Docomomo International** / Uta Pottgiesser

25 **The Role of Modern Architecture in Shaping Tomorrow** / Ana Tostões

28 **Docomomo. Then, Now, and the Future** / Maristella Casciato

30 **Revaluing Docomomo** / Huber Jan Hencket

33 **SUSTAINABLE DEVELOPMENT**

A. ADAPTIVE REUSE: IMPROVING BY DESIGN

34 **01. ORIGINAL DESIGN INTENT, LAYERS OF HISTORY AND THE NEED FOR ADAPTATION TO A CHANGING WORLD**
Chair: Scott Bruce Robertson

34 Original Design Intent, Layers of History and the Need for Adaptation to a Changing World / Scott Bruce Robertson

42 Decline of Department Stores and the Issue of 'Third Places' in German Inner-cities: Decline, Obsolescence and Reuse Potentials / Anica Dragutinovic, Uta Pottgiesser

48 Adaptive Reuse of Modern Heritage: Attitudes in Relation with the Materiality of Déjà la. Case Study of the Citroën Garage (1934) Becoming Kanal (2018) / Chiara Fucelli

55 The Ocean Terminal Complex, Durban: The Search for Meaning in an Irrevocably Changed Context / Mike Scurr

62 Narrating the Layers of History: Exploring Temporal Changes and Practical Realities in School Building Renovations /Meric Altintas Kaptan, Aslihan Unlu

70 The Weissenhof Estate from the Point of View of the State Research Society for Economics in Construction and Housing (Reichsforschungsgesellschaft für Wirtschaftlichkeit im Bau- und Wohnungswesen, RFG) / Edyta Naworska

77 **02. NOTABLE RENOVATIONS IN ORDINARY CONTEXTS**
Chairs: Ana Carolina Pellegrini, Danilo Matoso Macedo

77 Notable Renovations in Ordinary Contexts / Danilo Matoso Macedo, Ana Carolina Pellegrini

84 A Church Changes Confession – a Transformation Project with Aesthetics between East and West in Munich (1980-1995) / Korinna Zinovia Weber

91 Pinacoteca Contemporânea / Carlos Alberto Maciel, Paula Zasnicoff

98 West Bund Shanghai. Think Tank for Art / Jacopo Benedetti, Carlos Eduardo Comas

106 Corporate Architecture in Brussels: From Obsolescence to Heritagisation. La Royale Belge as case-study / Jean-Marc Basyn

114 Preserving Through Transforming. Exploring the Conversion Processes of Emery Roth and Sons' Post-War Office Buildings in Manhattan into Residential Spaces / Caterina Barioglio, Elena Guidetti

121 **03. TYPOLOGICAL EXERCISES AND THE SINGULARITY OF ITERATION**
Chair: Maximiano Atria

121 Typological Exercises and the Singularity of Iteration / Maximiano Atria

125 The Confines in the Architectural Type Definition: The Modernity of Airport Terminals in the Extreme Regions of Chile / Boris Cvitanic-Diaz, Claudio Galeno-Ibaceta

132 Flexibility in School Architecture: The 1970s Mat-Buildings of Recife, Brazil / Larissa Morgana Leão Silva de Sousa, Fernando Diniz Moreira

139 The Gasometer in Viena / Markus Tomaselli

146 Concrete Abstraction / Jorge Gambini

153 Researching, Dismantling, Rebuilding: The Work of Emilio Duhart Revealed by Intervening on the Herman House / Loreto Lyon, Alejandro Beals

B. WELLBEING FOR ALL: SPACES FOR INCLUSIVE AND EQUITABLE LIVING

161 **04. EDUCATING MODERN CHILDREN**
Chairs: Louise Noelle Gras Gas, Catherine Rose Ettinger

161 Educating Modern Children. Local Solutions and Standardised Construction / Louise Noelle Gras Gas, Catherine Rose Ettinger

167 Learning through Experience: Johann Heinrich Pestalozzi's Pedagogy in Hannes Meyer's Educational Building Projects / Raquel Franklin Unkind

174 Infrastructures of Child-Care: Establishing the Modern Language of Zagreb's Schools in the Agency of Ivan Zemljak / Mia Roth-Čerina

181 Cheste Worker University: Designing a Modern Educational Center Tailored for Children / Fernando Usó Martín, Maite Palomares Figueres

189 Pedagogical Experimentation and Modern Architecture: Experimental High Schools in Santiago, Chile / Ursula Exss

196 A Classroom to Change the World: The School Architecture of the Ministry of Public Works of Uruguay (1954-1965) / Alfredo Peláez Iglesias

203 **05. ADOPTION OF REUSE AND SUSTAINABLE CONSERVATION FOR EDUCATIONAL SPACES IN THE MODERN ARCHITECTURE**
Chairs: Zainab A. Murtadhawi, Ula Merie

203 Adaptive Reuse and Sustainable Conservation for Modern Educational Architecture / Zainab A. Murtadhawi, Ula Merie

210 Repurposing Modern Heritage Schools in Kuwait: A Framework for Adaptive Reuse / Rabab Raes Kazem, Naser Ashour

219 Ideas Behind the Form: Overlooked Qualities of the Experimental School in Bratislava / Nina Bartošová

226 Social Sustainability through Adaptive Reuse. Case study: Mt. Pleasant High School, USA / Armita Eghbali, Maya Weber

234 School Architecture and Adaptive Reuse: The Case of the Inmaculada Concepción School / Verónica Esparza Saavedra

241 Collaborative Redesign of Modern Schools: Rethinking Spaces of Coimbra Lyceum / Gonçalo Canto Moniz, João Mendes Ribeiro, Carolina Coelho, Pedro Brígida, Duarte Miranda, Valentina Gutiérrez

250 **06. HEALTHCARE COMPLEXES: THE FUTURES OF MODERN URBAN ENCLAVES**
Chairs: Claudio Galeno-Ibaceta, Ana A. Amora

250 Healthcare Complexes: The Futures of Modern Urban Enclaves / Claudio Galeno-Ibaceta, Ana A. Amora

257 The Power of Adaptation: The Convertion of a Teaching Hospital into a Justice Complex / Ivo Renato Giroto

264 Paimio Sanatorium – The Masterpiece in Change / Jonas Malmberg

272 Obsolescence and Vulnerability of Modern Hospital Heritage. The Challenge of Rural Psychiatric Hospitals in Mexico / Iván San Martín Córdova

279 Lelé's Architecture of Care: The Sarah Kubitschek Hospitals as a Strategy for Birth Centres and Healthcare Spaces / Carla Zollinger

286 The Instituto de Puericultura e Pediatria Martagão Gesteira (IPPMG). Between Glory and Risk / Helio Herbst

C. SUSTAINABLE TECHNOLOGIES: RESEARCH INTO ACTION

293 **07. CIRCULAR ECONOMY AND BUILT HERITAGE: OBSOLESCENCE, CIRCULARITY, INSTRUMENTS AND FUTURE**
Chairs: Renato D'Alencon, Dominga Teillery

293 Circular Economy and Built Heritage: Obsolescence, Circularity, Instruments and Future / Renato D'Alencon, Dominga Teillery

300 Stubborn Architecture: Preindustrial Principles of Slowing Building Material Use in the Use-Stage / Tobias Hentzer Dausgaard

307 Everyday Residential Heritage and Circularity: Potential and Limitations of Docomomo Full Documentation Fiches / Claudia Massioni, Wido Quist, Roberto Cavallo

315 Assessing the Environmental Impact: Office Building Reuse as a Sustainable Alternative to Demolition / Taylor Rose Quibell, Mario Santana Quintero

323 Curtains for Crown Hall: A Bioplastic Adaptation / Ryan Leigh Roark

330 Has Fossil Modernism Led us to a Dead End? / Wolfgang H. Salcher

337 **08. CONCRETE LONG-SPAN BUILDINGS' ADAPTIVE REUSE: SUSTAINABLE RETHINKING OF PUBLIC ARCHITECTURE AND INDUSTRIAL HERITAGE**
Chairs: Francesco Romeo, Giovanni Multari

337 Concrete Long-Span Buildings' Adaptive Reuse: Sustainable Rethinking of Public Architecture and Industrial Heritage / Francesco Romeo, Giovanni Multari

345 What if? Open Questions and Design Scenarios on the Upcycling of Long-Span Structural Components from 20th Century Authorial Architecture / Alberto Bologna, Margherita Maurea

352 Vilnius Concert and Sports Palace – Transformation of the Preservation Approach / Aušra Černauskienė

359 Methodological Approaches Through the Use of Advanced Information Systems (BIM-GIS and CDE) for the Management and Valorisation of 20th-Century Industrial Heritage / Antonio Maria Nese

366 Re-inhabiting the Modern Factory: The Former Milk Plant by Luigi Cosenza / Francesco Iuliano, Lorenzo Renzullo

373 The Marchiondi Spagliardi Institute and the Marxer Institute: Good Practices for the Care of Reinforced Concrete and New Forms of Dialogue with Existing Spaces / Bianca Maria Rodriguez, Chiara Assante

380 **09. PREFABRICATION IN REINFORCED CONCRETE AND INTERNATIONAL TRANSFERS DURING THE TWENTIETH-CENTURY**
Chairs: Pedro Ignacio Alonso

380 Towards a History of International Transfers in Large-Concrete Panel Systems / Pedro Ignacio Alonso

386 The Birth of Stavoprojekt, a Socialist Attempt to Collectivise Design Practice and Standardise Buildings and Technology / Petr Vorlík

394 Transposing the Discourse of Industrialised Construction in Housing Between Lisbon and Luanda During the 1970s / Inês Lima Rodrigues

401 The Role of Prefabrication in Housing Construction in the 1970s in China: The Case of Diplomatic Residential Compounds in Beijing / Yimei Zhang

407 Exporting Soviet Monumental Art from Soviet Tashkent to Europe and Siberia: The Works of Alexander, Nikolai and Pyotr Jarsky between 1969 and 1999 / Philipp Meuser

415 **D. BETTER CITIES: APPROACHES TO MODERN VALUES**

10. RESHUFFLING URBAN LAND: MODERN IDEAS FOR NEW URBAN MORPHOLOGIES
Chairs: Francisco Díaz, Marco Trisciuoglio

415 Reshuffling Urban Land: Modern Ideas for New Urban Morphologies / Francisco Díaz, Marco Trisciuoglio

422 The Drivers and Outcomes of the Urban Renewal in Oklahoma City: Looking Back, Looking Forward / Selena Bagnara Milan

428 Building the Model City of Socialism: Post-WWII Reconstruction of Nemiga Street in Minsk, Belarus / Dasha Kuletskaya

435 CIAM Young Generation's Ideas of the Street as a Tool to Question Conventional Hierarchies of Postwar Spatial Structuring / Elena Giaccone

442 Alternative Cities. The PEVE Programme, Mass Housing Proposals, and Urban Form Transitions in 1970s Argentina / Santiago Gomes

449 The Lot in Modern Architecture Urban Planning: The Case of Brasília Pilot Plan's Central Sectors, 1957 / Helena Bender

456 **11. 'INFORMAL' MODERNISMS: URBAN DESIGN, PLANNING NARRATIVES, AND NEW CITIES**
Chairs: Kuukuwa O Manful, Emmanuel Kusi Ofori-Sarpong

456 'Informal' Modernisms: Urban Design, Planning Narratives, and New Cities / Kuukuwa O Manful, Emmanuel Ofori-Sarpong

462 Palmas (TO): Contradictions among the Ways of Living in a New City's Block / Mariana Verdolin dos Santos

469 The Work Encampment: A Utopia by Rodrigo Lefèvre / Ana Carolina Buim Azevedo Marques, Ana Paula Koury

476 Socialist Practice of Modern Planning in the 1950s'China: the Case Study of Minhang Satellite Town and the Associated Rural Planning Project / Pengcheng Zeng

483 Narratives-Within a Narration: Bridging Modernism and Cultural Identity in African Literature and Architecture / Ntetleng Orepa Mosidi

490 Between the *Musseque* and the Neighbourhood Unit: Spotting "*Compagnons de route*" Architectures in Luanda (1961-1975) / Ana Vaz Milheiro, Leonor Matos Silva

496 **12. THE NATURAL HOUSE IN THE MODERN CITY: IDEOLOGICAL PRINCIPLES, TECHNICAL DEVICES AND URBAN PROJECTS**
Chairs: Joaquin Medina, Horacio Torrent

496 The Natural House in the Modern City: Ideological Principles, Technical Devices and Urban Projects / Horacio Torrent, Joaquín Medina

502 The Growing City. The Hybrid Character of Nature in Schwagenscheidt's *Raumstadt* Concept / Moran Lev

510 From Eden to Babylon. The role of Nature in Lima's Neighbourhood Units / Sharif S. Kahatt

517 Modern Housing Production on the Axis of Industry: The Expanding Boundaries of Istanbul / Yıldız Salman, Burak Ozturk

523 Villages, Houses and Gardens. Catholicism's Contribution to Social Housing in Uruguay / Mary Mendez

530 Devices for the Perception of Nature. Richard Neutra's Suburban Single-Family Houses / Matthias Brunner

E. CONTEMPORARY LIFE AND THE MODERN PUBLIC SPACES

536 **13. ADAPTING MODERN PUBLIC SPACE TO ACTUAL NEEDS**
Chairs: Elke Schlack, Juliane Von Hagen

536 Adapting Modern Public Space to Actual Needs / Elke Schlack, Juliane Von Hagen

543 Take the Heat: Adapting Modern Public Space to Accommodate Older Adults' Needs / Ana Martins, Gisela Lameira, Ana Silva Fernandes, Rui Jorge Garcia Ramos

550 Public Space for Childhood, Art and Biodiversity in Burle Marx's Plaza Perú in Buenos Aires: Between Documenting and Demolishing or Restoring and Rebuilding / Martín Capeluto

557 Redefining the Role of Public Space as an Urban Connector in the Lord Cochrane Housing Complex in Viña del Mar / Anna Braghini

564 Open Spaces in Modernist Housing Complexes: Urban Ambiance in Three Cases of Santiago de Chile / Ximena Arizaga

571 Adapting a Brussels Urban Regeneration Tool to the Specific Characteristics of a Large Social Housing Estate. The Case of the Sustainable Neighbourhood Contract (CQD) Peterbos / Morgane Bos, Giulia Marino, Alexandre Bossard, Chiara Cavalieri

579 **14. COMMUNITY LIFE AND MANAGEMENT OF NEIGHBOURHOOD UNITS**
Chairs: Flavia Brito Nascimento, Umberto Bonomo

579 Community Life and Management of Neigbourhood Units / Umberto Bonomo, Flavia Brito Nascimiento

586 The Implementation of the Salvador Residential Complex: From Modern Conception to the Contemporary Appropriation of its Common Spaces / Joaquim Nunes Junior, Ana Carolina Bierrenbach, Aline Maria Barroso

593 Just Patios Make Cities? A Review of the Town Planning Associates Project in Maracaibo, Venezuela / Andrea Castro Marcucci, Daniel Belandria Gutiérrez

600 The Empart I Housing Complex in Iquique, Chile. Collective Housing in a Desert Landscape / Victor Valenzuela-Grollmus

606 Re-negotiating Modernity: Appropriation and Everyday Life at Centro Urbano Antonio Nariño in Bogotá, Colombia (Liliana Andrea Clavijo García

613 Social Housing and Urban Ideals: A Case Study of Quito, Ecuador / Verónica Vaca Proaño, Néstor Llorca Vega, Enrique Ferreras Cid

621 **15. RE-EXAMINING THE MODERNIST CIVIC BUILDINGS FROM THE "GLOBAL SOUTH"**
Chairs: Ying Zhou, Cecilia L. Chu

621 Civicness and Tropicality: Re-examining the Modernist Civic Buildings from the "Global South" / Ying Zhou

627 Urban Textured Paintings: Exploring Chen Chi-Kwan's High-Rise Modern Architecture and Overall Ink Paintings from the "Global South" / Ning Tsai

635 Architecture for Children: Colonial Architects, Climate Design and Enduring Nursery Buildings (1957-1964) / Ana Vaz Milheiro / Beatriz Serrazina, Inês Lima Rodrigues

642 Between Tropicality and Modernism: Exploring Robert G. Boughey's Architectural Synthesis in the Global South / Fatema Tasmia

649 Flexible Architecture for New Education: Nordic Institute for Development Management (IDM) in Tanzania / Maryia Rusak

F. LANDSCAPES AND TERRITORIES OF THE MODERN: TODAY AND TOMORROW

655 **16. POST-INDUSTRIAL LANDSCAPES: PROJECTING VALUES AND USES FOR NEW LIFE CYCLES IN THE ANTHROPOCENE**
Chair: Osvaldo Moreno

655 Post-industrial Landscapes: Projecting Values and Uses for New Life Cycles in the Anthropocene / Osvaldo Moreno

661 Spring Bay Mill; The Transformation of a Peculiar Modern Industrial Heritage Site / Ross Brewin

668 Modern Pre-existing Structures and Urban Renewal: Cristina Xavier's Intervention at the Headquarters of O2 Filmes / Monica Junqueira de Camargo

675 Working on the Landscapes of Labour Between Ancient and Modern: Pin-point Projects for Industrial Archaeology in Tivoli / Edoardo Currà, Spartaco Paris, Carlo Vannini, Andrea Bonamore

683 Modernism on the Post-Industrial Riverfront: Heritage Site or Obsolete Relic? / Elizabeth M. Keslacy

690 The Social Construction of Post-industrial Heritage Values in Poblenou: New Urban Landscape Visions / Melina Guirnaldos Diaz

697 **17. RADICAL ROOF GARDENS: DREAM SPACES OF SOCIAL COHESION AND PRIVATE RETREAT**
Chairs: Nathaniel Robert Walker, Joseph Watson

697 Radical Roof Gardens: Dream Spaces of Social Cohesion and Private Retreat / Joseph Michael Watson, Nathaniel Robert Walker

703 Caipiras' Roof Gardens in Rio de Janeiro / Silvana Nicolli

710 The Itamaraty Palace Roof Garden and a Possible Image of Brazil / Ana Paula Polizzo

716 One Thousand and One Flights: A Rooftop Airport Oasis in the Arabian Desert / Joss Kiely

722 A nocturnal roof garden for spectacles. The Luminous Ship by Carles Buïgas / David Caralt

729 **18. MODERN HERITAGE AND URBAN PRODUCTION**
Chair: Magdalena Vicuña

729 Modern Heritage and Urban Production / Magdalena Vicuña

733 Addressing the Modernist Legacy Through the Historical Townscape: Re-evaluating Public Architecture of the 1970s-1980s in Ghent (Belgium) / Evert Vandeweghe

740 Modern Urban Landscape: Traces of Identity, Vectors of Sustainability. The Case of the Matthei Neighbourhood in Osorno / Hugo Weibel Fernández

747 Sun, Space, Greenery and Global Warming. The Potential of the Modern Housing Landscape in Climate Change Mitigation / Rodrigo Gertosio Swanston

753 Urban Values Heritage: Gilberto Gatto Sobral's Modern Architecture in Cuenca, Ecuador / Paola Preti, Fernanda Aguirre, Veronica Heras

759 Architecture of the Property State: Public Ownership of Land & the Production of the Built Environment in Post-Independence Singapore / Jacob Meyers

766 **19. MODERNISM AND DIPLOMACY: PAYING IT FORWARD AT U.S. EMBASSIES (ROUND TABLE)**
Chairs: Kathleen Gerner, Jorge Salcedo

766 Modernism and Diplomacy: Paying it Forward at U.S. Embassies / Jorge Salcedo

774 Case Study: The Major Rehabilitation and Expansion of the U.S. Embassy in Athens Greece, Originally Designed by Walter Gropius (1959-1961) / Kathleen Gerner

779 A Case Study in Modernism and Diplomacy: The Major Rehabilitation and Restoration of the Brutalist U.S. Embassy in Montevideo, Uruguay, Originally Designed by I.M. Pei (1959-1969) / Troy Thompson

785 Case Study: Historic Intent and the Renovation of Eduardo Catalano's U.S. Embassy in Buenos Aires / Juan Villafañe

792 Maintaining Cultural History and Meeting 21st Century Expectations – Embassy in Montevideo as Example for Major Diplomatic Renovations / Frederick J. Poehler

CULTURAL DIVERSITY

798 **A. RESEARCH AND DISSEMINATION AS OPEN FIELDS**

799 **20. ENGAGED RESEARCH: EXPLORING AND STRUGGLING FOR THE ARCHITECTURE OF WELFARE STATES**
Chairs: Peter Szalay, Henrieta Moravčíková

799 Engaged research: Exploring and Struggling for the Architecture of Welfare States / Peter Szalay, Henrieta Moravčíková

806 Continuity and Transformation of Post-War Modernist Architecture: The Case Study of the Former Communist Party Headquarters in Košice, Slovakia / Monika Kicová

812 Away from Nostalgia: A New Approach for the Forgotten Welfare State Industrial Facilities / Maximiano Atria

818 Wider than Welfare: Industry, Infrastructure and Eradication / Richard Brook

824 The Aylesbury Estate: Shifting Narratives on Urban Renewal / Lucia Concetta Vincelli, James Aston Lansbury

831 Architectural Conservation and Political Resilience: The 2023 Attack on the Palace of Congress in Brasilia / Danilo Matoso Macedo, Ana Carolina Pellegrini

838 **21. INTERDISCIPLINARY APROACHES**
Chair: Paulo Dam

838 Transdisciplinary Approaches in the Construction of the Modern: Peru as a Quest / Paulo Dam

844 Margarete Schütte-Lihotzky's Innovative Schools: The Modern Revolution of Objects / Mara Sánchez Llorens, Fermina Garrido López

852 Libeskind House: The Construction of a Modern Ambience Trough the Protagonism of Joaquim Tenreiro's Work / Luciana Tombi Brasil

859 Digital Documentation Workflows and Training for the Conservation and Planning of Niki de Saint Phalle's Tarot Garden / Mario Santana Quintero, Flavia Perugini

866 The Link Between Architecture and Psychology in Japan: Yoshinobu Ashihara's Landscape Theory / Zahra Ramezani, Kenji Watanabe

874 **22. MODERN MOVEMENT AS A MEDIUM FOR EXPRESSION AND AS A DISSEMINATION TOOL IN AUDIOVISUAL MEDIA**
Chairs: Susana Landrove Bossut, Sara Pérez Barreiro

874 Modern Movement as a Medium for Expression and as a Dissemination Tool in Audiovisual Media / Susana Landrove Bossut, Sara Pérez Barreiro

880 Stimulating Historical Identity through Alternative Media / Emma Veronese

887 Towards a New Metropolis: The Machinist Utopia in Urbanism and Cinema / Luciano de Topin Ribeiro

894 Experiences of Modern Space in the Central Valley of Chile / Glenn Deulofeu

901 Exploring Late-Modernist Domesticity in a Wooden Flexible House Versus a Concrete Brutalist House / Els De Vos

907 Parafictions of the Glitched Estate in Central Hill / Alessandro Columbano

B. SCOPE OF MODERN: EXTENTS AND APPROACHES

914 **23. BEYOND MODERNISM**
Chair: Lidwine Spoormans

914 Beyond Modernism / Lidwine Spoormans

921 Portuguese Architecture in the 1980s: Into a Dreamlike Everyday Life / Jorge Figueira

929 Irony and Experimentation in Jaretti and Luzi's Architecture (1960-1974) / Maria Luisa Barelli, Davide Rolfo

936 Parque Guinle Post-Modern? / Nathalia Cantergiani, Mara Eskinazi, Mônica Luce Bohrer

944 French New Towns: Last Avatar of the Welfare State or New Avant-Garde Proposals? / Catherine Blain

951 Modernism and Countercultural Architecture: Not Exactly a Neat Cut-Off / Elena Poma, Franz Graf

958 **24. MONUMENTAL MODERNISM: LEGACY OR WASTE?**
Chairs: Claudia Costa Cabral, Fernando Diez

958 Monumental Modernism: Legacy or Waste / Claudia Costa Cabral, Fernando Diez

965 Housing Problem in Italy and Large-Scale Buildings in Second Half of the 20th Century. A Fragile Heritage / Francesca Albani

971 Mending Wall – Continuity in the Modernist City: Interpreting Smallbrook Ringway Centre, Birmingham / Michael Dring

978 New Old London: Modern Large-Scale Housing for the Traditional City / Jaime Silva, Ana Tostões

985 Ibirapuera Gymnasium: Renewal of Use, Private Concession and Preservation in São Paulo / Renato Anelli

992 Revisiting Merihaka's Parking Structures P1 and P2 / Karita Rytivaara

1000 **25. BEYOND CIAM: TRANSNATIONAL NETWORKS OF LATE MODERNISM**
Chairs: Marta García Carbonero, Brett Tippey

1000 Beyond CIAM: Transnational Networks of Late Modernism / Marta García Carbonero, Brett Tippey

1007 Situated and Creative. Two Acts on Housing Design, Participation, and Methods in Latin American Late Modernism / Guido Campi

1013 Exploring Beyond Borders: The Significance of *Pequeños Congresos* in the Valuation of Spanish Architecture / Ana Esteban Maluenda

1020 From Valparaíso to Vancouver: Pan-American Networks and Poetic Visions of a Unified America / Oscar Andrade Castro

1026 Unveiling Post-Independence Discourse of Modern Indian Architecture: Insights from *Design Magazine* (1957) / Pappal Suneja

1032 Prishtina Shunning Critique: Yugoslavia's Encounter with the Radical Architecture Movement / Edmond Drenogllava

C. THEORIES AND HISTORIES IN TIMES OF CONTROVERSY

1039 **26. AUTHENTICITY IN THE FACE OF CLIMATE CHANGE**
Chairs: France Vanlaethem, Éve Wertheimer

1039 Authenticity in the Face of Climate Change / France Vanlaethem, Eve Wertheimer

1046 Preserving Authenticity after Seismic Retrofit and Reuse in Japan / Toru Ajisaka

1051 Bridging Cultural Significance and Risk Assessment: Compared Analysis from Conservation Management Plans in Portugal and Cuba (1960-1966) / Teresa Cunha Ferreira, Davide Del Curto, Pedro Murilo de Freitas, Andrea Garzulino, Rui Fernandes Póvoas

1059 A Comprehensive Framework to Increase Modelling Credibility in Modern Buildings Energy Simulations. The Case Study of Chauderon Complex Façade by Jean Prouvé in Lausanne (1969-1974) / Giuseppe Galbiati, Franz Graf, Giulia Marino

1065 The Sustainable Shine Dome: Toward a Sustainability Plan for the National Heritage Listed Australian Academy of Science Building / Michael Jasper, Tracy Ireland

1071 **27. NONCANONICAL CURATORIAL NARRATIVES. RETHINKING THE ROLE OF THE ARCHITECTURE EXHIBITION**
Chairs: Maria Cristina Cabral, Ana Esteban Maluenda

1071 Curatorial Narratives: Rethinking the Role of the Exhibition / Maria Cristina Cabral, Ana Esteban Maluenda

1077 Presenting Architecture, the Archive and Microhistories: The Opening Exhibition of the New Home of Hungarian Architecture / Ágnes Anna Sebestyén

1083 A New Period Eye: Learning to See Venezuela's Modernity with Docomomo Venezuela Exhibitions / Frank Alcock

1091 Beyond Modernism: Curatorial Clashes and Transformations in 1983 Portuguese Architectural Exhibitions / Ana Neiva

1098 War's Toll of Italian Heritage: Unveiling Italy's Postwar Reconstruction through Transnational Exhibitions / Jiayao Jiang

1105 Contested Modernities: Architecture and Propaganda in the *Exposição Nacional do Estado Novo* (Rio de Janeiro, 1938) / Catarina Flaksman

1111 **28. REMAPPING MODERNISMS: CONTEMPORARY DEBATES**
Chairs: Ruth Verde Zein, Patricia Santos Pedrosa

1111 Remapping Modernisms: Contemporary Debates / Ruth Verde Zein, Patrícia Santos Pedrosa

1118 The Narrative Triad of Nikolaus Pevsner: Recognising the Content Profile and Structure of the Book *Pioneers of Modern Design* / Tais Ossani

1125 Lina Bo Bardi: the Bad and the Ugly - Contemporary Formal Problems / Patricia Pereira Martins

1132 Being Modern, Building Modern. *L'Union Féministe Egyptienne's* headquarters in Cairo in 1932 / John Hanna, María Novas Ferradás

1138 The Value of the Material. An Economic Re-reading of the Modern Ideal in Chile / Paula Orta Camus, Cristian Muñoz Díaz

1146 Towards a Transient Understanding of Modern Built Heritage Documentation and Research / Adina Hempel

D. CONSERVATION TRAINING: THE PAST AND THE FUTURE

1154 **29. HOW CAN EXHIBITIONS HELP CREATING A SUSTAINABLE AND RESPONSIBLE ATTITUDE TOWARDS THE FUTURE?**
Chair: Bárbara Coutinho

1154 How can Exhibitions Help Creating a Sustainable and Responsible Attitude Towards the Future? / Bárbara Coutinho

1160 Towards a Reparative Architectural History / Eduardo Augusto Costa, Junia Cambraia Mortimer

1167 Discovering a New Narrative: Interpretation Method Practices in the Exhibition *Modernism for the Future 360/365* / Viltė Migonytė-Petrulienė

1174 Archive Narratives. Curatorial proposals based on archive collection documents / Michelle Llona Ridoutt

1180 Elizabeth Mock's Curatorship at MoMA: a New Approach to Architecture and Architecture Exhibitions and its Echoes in Europe / João Miguel Couto Duarte, Maria João Moreira Soares

1187 Food Party: Reflections on Community Engagement through Food Projects in Architectural Exhibitions / Leyuan Li, Max Bravo

1194 **30. EDUCATION TO CONSERVE MODERN HERITAGE: METHODS AND TOOLS**
Chairs: Chandler McCoy, Andrea Canziani

1194 Education to Conserve Modern Heritage: Methods and Tools / Andrea Canziani, Chandler McCoy

1201 The CMAI's International Training on the Conservation of Modern Heritage / Margherita Pedroni

1209 Joint Master RMB, Re-use of Modernist Buildings / Michel Melenhorst

1217 The Conservation Planning as a Contribution to Education and Training for Twentieth-century Heritage Conservation / Santiago Beckdorf

1224 Remapping Modernism: MAPA Peru Arequipa 2023 / Carlos Torres Flores, Mariano Quiroga Robles, Rosabella Alvarez-Calderón Silva Santisteban

1232 What Do We Want from Architectural Education? / Artina Qehaja

1239 **31. RE-EDUCATION FOR REUSE OF MODERN SPACES. SOCIAL AND ENVIRONMENTAL DIMENSION AS A PLATFORM FOR INCLUSIVE DIDACTIC AND RESEARCH**
Chairs: Carolina Quiroga, Gonçalo Canto Moniz

1239 Re-education for Reuse of Modern Spaces. Social and Environmental Dimension as a Platform for Inclusive Didactic and Research / Gonçalo Canto Moniz, Carolina Quiroga

1246 Education, Research, and Extension Practices on Sorocaba City (Brazil) Modern Architectural Heritage / Taiana Car Vidotto

1254 Implementing Democracy in Socialist Architecture. Adaptation of Former Soviet Schools for Contemporary Education Needs in Lithuania / Liutauras Nekrosius, Dolf Broekhuizen

1261 Pimp Danish Modernism: Drawing as a Pedagogical Tool for a Sustainable Future / Angela Gigliotti, Fabio Gigone

1268 Transforming a Conventional Rigid Classroom into a Stimulating Space / Adéla Šoborová

1276 (Re)signifying and (re)designing Modern School Playgrounds. Experiments on Collaborative Design in Portugal / Patrícia Lourenço, Alexandra Alegre, Teresa Heitor

E. EVERYDAY LIFE AND MODERN INTERIOR

1285 **32. ADAPTIVE MODERN HOUSING: SHIFTING NOTIONS OF COMFORT AND THE TRANSFORMATION OF DOMESTIC SPACE FOR CONTEMPORARY LIVING**
Chair: Zara Castelo Ferreira

1285 Adaptive Modern Housing: Shifting Notions of Comfort and the Transformation of Domestic Space for Contemporary Living / Zara Castelo Ferreira

1292 Modern Archaeologies: Sustainable Strategies for Social Housing Building in Athens, 1950-1970 / Chrysostomos Theodoropoulos

1300 Spatial Decolonisation of the Modern Middle-class Housing of Mozambique / Patricia Noormahomed

1308 Departure from the Chandigarh Style: Contemporary Adaptations to the Regulated Marla House / Priya Gupta

1315 Reflections on Minimum Space Living in Macau / Niccolò Arnaldo Galliano, Ana Tostões

1323 Exploring the Evolution of the Mass-Empty Space Relationship for Social Sustainability in Shushtar New Town: Insights from Kamran Diba's Design / Parisa Etemadi, Helder Casal Ribeiro

1330 **33. CAPTURING TIME INSIDE ARCHITECTURE**
Chairs: Ana Tostões, Marta Silveira Peixoto

1330 Capturing Time Inside Architecture / Ana Tostões, Marta Peixoto

1337 Recognizing Cultural Values in Changes to Modern Interiors / Juliano Loureiro de Carvalho

INTRODUCTION

The Faculty of Architecture, Design and Urban Studies (FADEU) of the Pontificia Universidad Católica and Docomomo Chile are honoured by the trust placed in us by Docomomo International and the community dedicated to modern heritage, to host the 18th International Docomomo Conference and Students Workshop from 4 to 14 December 2024, at the Lo Contador Campus, in Santiago de Chile, where we will discuss the theme "Modern futures: sustainable development and cultural diversity." This Conference seeks to highlight the exploration and development of new ideas for the future of a sustainable built environment, grounded in the past experiences of the Modern Movement, and address cultural diversity as one of a key aspect of any vision for the future.

Since accepting our proposal, we have worked tirelessly to ensure that this meeting, in a country often considered distant, feels closer to all who wish to join us. The Conference, Workshop, tours, pre-events and side events have all been organised with these objectives in mind. The 18th International Docomomo Conference will feature seven keynote lectures, 38 paper sessions, two roundtables, two workshop sessions, two MoMo EWI sessions, an international workshop (4-10 December) and MoMo tours in Santiago, Valparaíso, Viña del Mar, and Ritoque. To foster diverse approaches to the conservation, sustainable development and cultural diversity of modern heritage, the organisation launched a preliminary call for sessions, which proved to be a success, with 79 proposals received and 40 sessions accepted. The call for papers garnered 512 proposals, of which 226 were selected and reviewed for publication. This book is the result of a rigorous process of selection and review, carried out by a tireless and excellent Scientific Committee of experts from around the world, to whom we owe our deepest gratitude.

At this Conference, we have also established the Modern Movement Educational Worldwide Initiative (MoMo -EWI), inviting schools of Architecture, Urban Planning, Landscape, and Preservation to join this initiative by teaching courses, design studios, workshops, theses, or specific training experiences related to the conference themes. In this spirit, MoMo-EWI seeks to emphasise modern heritage as a central topic in teaching at a graduate and post-graduate level. This initiative will showcase various teaching and learning activities, presenting the outcomes of undergraduate, master's and doctoral courses. It has attracted many stakeholders from across the globe, and we believe it can be a powerful tool for educating future generations and for sharing knowledge in our field.

One of our key priorities has been the development of opportunities for student participation, because they will be the future protagonists in the field. Currently, 84 PhD students are participating in the Conference. The International Students Workshop has been carefully designed to address relevant urban and housing issues in Chile and other parts of the developing world. More than 40 undergraduate students will join us in this challenge, which was organised alongside the International Scientific Committee on Education and Training of Docomomo International. More than 20 teachers and tutors from various countries and universities have contributed to this effort. The Manifesto on Education has provided essential guidance for the International Students Workshop and has been well received by many universities that have joined us, recognising Docomomo's role in framing the architecture and urbanism of the Modern Movement as architecture's technical, formal, and ideological response to the contemporary world

We extend our heartfelt thanks to the Executive Committee and the Advisory Board for their trust and support over the past two years; the Scientific Committee, who did an outstanding job in reviewing session applications followed by academic papers; the tutors and professors of the International Students Workshop; the Docomomo chapters and everyone involved in the 16 pre-events organised throughout 2023 and 2024 to promote debate and present diverse works in which the community showcased its commitment to conservation, sustainable development and cultural diversity. Special thanks to the session chairs, authors and contributors who share their knowledge at the Conference and through this book; to the attendees from more than 40 countries; to our friends in Latin America, who have supported our work by accompanying us in this adventure; to the editorial staff of Ediciones ARQ and the proofreaders; and to the members of the organising committee here in Santiago, who have worked tirelessly to ensure everything runs as smoothly as possible.

We are also grateful to Docomomo International and its 80 —and growing— working parties around the world. With nearly three decades of existence, Docomomo has broad appeal and has gained an established position and global recognition. Docomomo Chile, founded 20 years ago, has since become a significant actor in the national context. Its seminars, publications, advocacy actions, responses in the face of national emergencies, and community engagement have given it a strong presence in Chile's cultural environment. International recognition reaffirms this long-standing work.

As the Faculty of Architecture, Design and Urban Studies of the Pontificia Universidad Católica, we are proud to welcome and support Docomomo Chile in its mission to promote the documentation and conservation of our architectural legacy and culture. Docomomo's collaboration with other cultural, political and social actors in Chile have made it as a key player in matters related to preserving our architectural and urban heritage. This work is becoming increasingly vital as Chile moves towards becoming a more sustainable and culturally diverse nation.

The organisation of the 18th International Docomomo Conference in Santiago is particularly relevant because of the attention and emphasis it brings to Chile's modern heritage, as well as that of Latin America and the South of the world, proposing a different future for modern heritage. During the 20th century, cities in South America saw extraordinary population growth, generating an accelerated urbanisation process and dramatic territorial transformations. Modern architecture played a critical role in shaping these cities and the buildings that society required. Early in the 1920s and 1930s, modern housing, schools, hospitals, and recreational centres were built in some of the most remote areas of South America. In Chile, the territory's particular geography implied the construction of modern architecture from the desert in the north to the frozen areas in the South. Modern architecture showed a different, more equitable possibility for society as a whole.

Today, Chile is at a turning point, with global change reshaping public policies. Society demands global care and greater justice in human relations, and the challenges of development and inclusiveness are keys to a better future. Modern architecture embodies standards and levels that current housing struggles to meet. Communities are reclaiming their relationship with green areas, low densities, and the presence of facilities as a part of their heritage. Chile is also strategically positioned as a key location where the needs of the Global South intersect with challenges of global integration, particularly in the Asia-Pacific region. Latin American culture, in turn, proposes new forms of social commitment through sustainable development and cultural diversity.

Our Faculty recognises, in the works of the Modern Movement, an enduring source of study and knowledge that is an example for our students. For many years, the modern buildings of Santiago, from the second half of the 20th century, have served as sublime references for generations of students. Thus, Chile, the "land of poets," copper, vineyards, and surprising landscapes, is also fertile in beautiful works inspired by the principles of the Modern Movement.

We hope that the Conference, the Workshop, and its activities will provide an excellent opportunity for the approximately 400 experts from around the world who meet in Santiago de Chile to share knowledge and contacts —as outlined in the Eindhoven-Seoul Statement— to "explore and develop new ideas for the future of a sustainable built environment based on the past experiences of the Modern Movement." Chile is the perfect place to do this. While you're here, we also hope you enjoy our landscapes, imposing geography, heritage, vibrant and diverse culture, friendliness, and desire to live better. Welcome.

Horacio Torrent

MODERN FUTURES: SUSTAINABLE DEVELOPMENT AND CULTURAL DIVERSITY

HORACIO TORRENT
CHAIR, 18TH INTERNATIONAL DOCOMOMO CONFERENCE

FUTURE

For some time now, the future has failed to spark any emotions. In fact, we appear to be so overwhelmed by the present that contemplating the future has become difficult. Yet, at the same time, we are becoming increasingly alarmed by the future as it has become clear that some actions taken globally are proving to be dangerous and worrying. Climate change, the uncertain future of our planet, social crises, the devaluation of democracy as a solution to our problems, the erosion of welfare ideals, and the material struggles faced by a large part of the world's population call into question the concept of the future. At the same time, some technologies foreshadow uncertain paths.

The future is not only a temporal condition but also a cultural construction. A profound understanding of the future as a cultural construct is revealed, as Arjun Appadurai has argued, "by examining the interactions between three notable human preoccupations that shape the future as a cultural fact, that is, as a form of difference. These are imagination, anticipation, and aspiration."[1]

There was no shortage of cultural practices that, at the dawn of the 20th century, addressed the imagination of the future. Literature, infused with technological optimism or social pessimism, envisioned possible worlds. Cinema boldly showcased alternative futures. Illustration and comics did their own thing as well. Frequently published, the image of a futuristic metropolis aimed to symbolise the future of many other cities such as Barcelona, New York or Buenos Aires. Imagination flourished in these depictions of the future city, anticipating its social and economic dimensions and territorial relationships as they sought to understand the new urban phenomena brought about by industrialisation.

The future city was the subject of extensive speculation across diverse fields, but primarily in architecture and urban planning. This exploration is not just an inherent anticipatory exercise within design; it gains significance through architects' ability to integrate a wide range of issues cohesively. It did so to such a degree that the very notion of modern architecture became inseparable from the city's project. The contributions of Garnier, Taut, Le Corbusier, Hilberseimer, Neutra and many others took shape in representations that contributed to understanding the city's future. Moreover, the technical analysis of a large sample of cities under the same framework has served as a basis for establishing some anticipatory rules.[2]

Aspirations for a better life were constitutive of the realities of modern architecture in countless places worldwide. Poor living conditions were a frequent feature of cities, housing needs were present in many settlements, and modern architecture made it possible to resolve them in a timely manner and in keeping with budgetary needs.

Modern architecture emerged from a mixture of social demands across different environments. The aspiration for a better society was always present, along with the need for aesthetic updates that would coincide with technological renovations reflecting basic aspirations in more than one place on earth. Modern architecture's social, cultural, and political dimensions have often been highlighted, even when the political convictions differed between protagonists worldwide.[3] However, the shared objective of preparing for the future remained a constant. These elements served as a cultural horizon that guided modern architecture.

Not so long ago, a wide variety of modern heritage essays, case studies in different geographical settings, and conservation projects illustrated the relevance of modern architecture elsewhere. In this sense, it is essential to note the exploration and development of new ideas for the future of a sustainable built environment based on the past experiences of the Modern Movement.

Sustainable development and cultural diversity challenge our knowledge and daily practice as architects and conservationists.

MODERN AND SUSTAINABLE

Modern architecture was undoubtedly the protagonist in an era rich in resources and inextricably linked to the material abundance of the Industrial Revolution. Various perspectives aimed to establish a technological relationship with this

new architectural style, which we observe in diverse instances of modern architecture. To deny the correlation between it and its effects on the environment would be irresponsible and misguided.[4] The relationship with technological innovation was of central importance on both a material and symbolic level.

The 20th century undoubtedly witnessed ecological transformations that radically changed the face of the earth. Infrastructure development for energy, transportation, and communications has historically gone hand in hand with architecture and urbanism. However, it is also true that many of these developments should not be attributed to Modern Architecture despite their significant contributions to its visual language. The phenomenon of urban growth has perhaps had the most significant impact on the very life of communities. The conversion of agricultural land or nature into the artificial condition of the city and its constant expansion, as well as the loss of urban legibility and the disintegration of communities and neighbourhoods, have been matters of concern. Many modern architects and urban planners raised concerns over the ecological transformations and urban phenomena, the latter of which was considered central to the Modern Movement's agenda. Urban issues often remained symbolic or disregarded contingent powers, though there were some notable exceptions. Climate played a pivotal role in urban construction concerning housing, as illustrated in Gropius' diagrams of block separation or Klein's or Hilberseimer's diagrams of insolation within the unit. Design directly related to climates, such as Wladimiro Acosta's Helios System or the various trials on porosity in modern Brazilian architecture, also reflects an approach to the scale of the architectural work. The dimension of landscape as part of ecological awareness was a determining factor in some of the non-central manifestations of modern architecture worldwide.

I am not setting out to prove they had a planetary or ecological conscience, but some certainly did. Richard Neutra warned about the responsibility of modifying the natural environment:

> "*All our expensive long-term investments in constructed environment will be considered legitimate only if the designers have a high, provable* index of livability. *Such designs must be conceived by a profession brought up in a social responsibility, skilled, and intent on aiding the survival of a race that is in grave danger of becoming self-destructive*."[5]

The phenomenon of sprawling cities has already become a global problem. At least half of the world's population resides in cities, and in some countries, the percentage of urban population is as high as 90%. Projections indicate that, globally, by 2050, 70% will live in cities. Today's situation is characterised by sprawling growth, air and waste pollution, pockets of extreme poverty, amounting to one-seventh of the world's population, and a lack of adequate public facilities and spaces.[6] At the same time, "cities occupy only 3 % of the earth's surface, but account for 60 to 80 % of energy consumption and 75 % of carbon emissions."[7] The international community claims that "by committing to sustainability, we choose to build cities where all citizens have a decent quality of life and are part of the productive dynamics of the city, generating shared prosperity and social stability without harming the environment." Although this may appear to be an illusion, it also represents a construction of a possible future where imagination, anticipation and aspiration come together once more. The goals for sustainable development provide us with a framework to consider the conservation of modern heritage associated with the necessary global transformations.

Sustainable development is a clear concept that focuses on improving life today while safeguarding the future. It involves conserving nature and the environment while ensuring their availability for future generations is not compromised. Essentially, we envision a future in which life thrives, we anticipate some measures to bring about the necessary improvement, and we hope future generations will benefit from what we value on our planet.

In this context, preserving modern heritage is essential for sustainability. During the 20th century, countless public facilities and social infrastructures were built, such as schools, hospitals, sports facilities, civic and cultural centres, churches and community centres, and places of work and residence. In several countries, modern architecture has reshaped the landscape. In quantitative terms, it has surpassed any dimension of previous cities and thus brought about both a change in their countenance and ways of life and social relations. Many housing estates produced using modern designs now face severe obsolescence regarding their sanitary infrastructures and energy consumption. Therefore, these areas require fundamental adaptation to maintain them in the future, not only as heritage but fundamentally as a place to live.

The world is becoming increasingly urbanised, and reusing spaces created by the modern movement becomes crucial for metropolitan and smaller cities, primarily because it introduced nature into the urban fabric. Communities

inhabiting these areas advocate for their right to a more inclusive city and an improved quality of life. Moreover, the modern movement's designs provide a better environment than the city built today.

Promoting modern heritage conservation requires disseminating appropriate techniques and methods adapted to different circumstances, places, and climates. Adaptive reuse serves as a sustainable approach to achieve conservation. Sustainability involves not just materials and energy but also considers social and meaningful aspects. Our commitment and understanding of preserving modern heritage contribute to the broader international agenda for sustainability.

MODERN AND DIVERSE

It is not just about being aware that there are others in this world, that we are not alone, and that it is not just us and those with whom we share our daily lives. It is about embracing diversity that exists around us, allowing an unrestricted environment for everyone.

This is not about merely expanding our knowledge by incorporating forgotten, despised or rejected characters, cultures, genders, and places. It is essentially about recognition, and understanding others and their circumstances as we understand ourselves.

Culturally, hegemonic knowledge is not univocal. The term "discovery" always comes as a surprise. It is not a univocal word. It carries different meanings for those who discover and those who are discovered. The discovered person does not identify as such because they know themselves. Perhaps it is time to recognise that there are many different perspectives, various epistemologies of alterity, and multiple approaches to gaining knowledge.[8]

Diversity is already a global demand. It involves fostering environments for cultures to flourish and interact freely in mutually beneficial ways, promoting interculturality to build bridges and reaffirming the importance of the link between culture and development.[9]

It is undoubtedly a tremendous challenge, but in the meantime, it seems fundamental to accept and promote diversity on a daily basis. Recognising others goes beyond having respect for them or recognising their dignity. It is also an exercise in knowledge. Once again, it is a battle against ignorance, especially the ignorance of the discoverers, of those who are considered knowledgeable. This represents a central paradox in this world.

The architecture of the Modern Movement spread throughout the world, taking shape in various locations where architects discovered sources of innovation, fresh knowledge, and creative impulses. The Modern Movement is often considered in its unitary condition, with histories and theories often highlighting its universal meanings. Nevertheless, diversity was assumed to be one of its topics. Therefore, many kinds of modern architecture exist in so many places.

When modern architecture took shape in the most diverse places around the globe, diversity was not a claim but rather a way of situating differences. While some modern architects championed the industrialisation of mass production and technical rationality, it is also true that many others asserted their designs more in the context, materials, tectonic expression and social conception of the programme. Many established notable differences exploring various social and political approaches, appropriate forms and technologies in the search for a conception free of prejudice. Numerous modern architects found inspiration and guidance in diversity, revealing a reality that was far more diverse than the narratives have suggested.

The now traditional historical interpretations echoed two common facets of Western thought: the visual perception of appearance and the vertical sequence of modernisation. On the one hand, the stylistic conception of architecture presupposes greater importance of the characters of buildings and their resemblances, rendering the global experience a unitary fact and setting aside all differences - in the system of creativity and production, which for other disciplines would be crucial to the characterisation of material culture. This approach treats the city as a neutral space, contrasting sharply with the unexpected consequences of visual unity.[10] On the other hand, the vertical sequence of modernisation assumes a theoretical orientation in which modernity spread through hierarchical structures where the major cities played a key role, accentuating the regularity of experience from the centre to the margins.

These views have existed for a long time and remain relevant, even today. The argument that elsewhere, there was a reproduction worthy of a paradigm - even if there are individual cases - is no longer valid to assume diversity as a fundamental condition.

Retro-transfers, crossings, and encounters have been studied for a long time, although their usual interpretation often remains unchanged. In a fundamental effort, it is necessary to focus on the specific events in each situation, considering the unique geographical and cultural contexts, rather than viewing them merely as reflections of what transpired elsewhere. The experiences of culture, including those of modern architecture, have much more diverse possibilities to explore and differences to focus on.

The debate on the legacy of the Modern Movement must address the differences, the diversity, and the need for a new global approach.

CODA

The cultural construction of a future for conserving modern heritage could engage the imagination, expectations and aspirations that characterised modern architecture. Imagination should be harnessed to reconstruct the material dimensions of the works and their alterations and to transcend form exploring unforeseen technological possibilities. The anticipation of the project will enable it to adapt based on a rich archive of past lessons learned. The aspirations represented by the ideas of human well-being and a fulfilling life are still valid.

The discomfort and uneasiness in the face of modernity have been present for a long time, partly because of some unitary historical interpretations and partly because of what it meant. In the 1980s, Jürgen Habermas reminded us not to abandon modernity and its project as a lost cause; instead, we should envision its possibilities for the future.[11]

While some of its components deserve to be revised and transformed in line with today's requirements, others require confirmation and continuity.

The belief in advancing modern architecture stems not only from the beauty of its works or the magnificence of its spatial transformations but also from the social aspirations and values that guided its actions in the different places where it was forged in response to local demands.

For years, modern architecture has been recognised as heritage in its many dimensions. Imagination must be present in the methods and ways of approaching the public and using new media.

Recording and valuing buildings, ensembles, sites, and landscapes of local, regional or global significance has been a fundamental proactive effort in recognising their social importance and transcendence in the quality of life of the people. It has been an exercise in recognition validated in the archives of collective memory.

The aspiration lies in making the values historically embodied by modern architecture more understandable in the different places in which it has acted, detaching itself from the very idea of its origin and responding to the diversity of practices and cultures in which its results were forged. There is no longer any possibility of maintaining a unitary interpretation of an event such as that of modern architecture, given its complexity, wide reach, and cultural variations.

Conversely, the reuse of the existing material values inscribed in the built assets and economic circularity conditions make sustainability a vital necessity for our efforts. We will encourage creative thinking by posing questions about the technical and technological processes for maintenance and restoration. Additionally, we will explore the design capacities to adapt modern heritage assets to current uses and conditions. An immense opportunity presents itself, allowing survival by design.

The recording, revising, and assessing of our proposed best practices over the years reflect an anticipatory understanding of the possibilities and restrictions of multiple conservation actions, adaptive reuse, or design integration with a new architecture.[12]

The aspiration is for modern architecture's teachings to remain relevant in our ways of life, in the urban fabric, and in the correspondence between the built and the natural. Furthermore, the works of modern architecture should point the way to its new possibilities, confirming that they serve as a foundation for its transformation.

With this basis, we can shape the future of modern heritage conservation culturally.

Horacio Torrent (Argentina, 1959) holds a PhD and MSc and is an architect, architectural critic and historian. He has researched modern architecture at institutions such as the Canadian Centre for Architecture, the Getty Institute for the Arts and the Humanities, the National Gallery of Arts in Washington, and the Iberoamerikanisches Institut in Berlin. His research focuses on the history of Modern Architecture and the city and on Latin American and Chilean architecture. Since 2004, he has served as Chair of Docomomo Chile and has been co-chair of the LA/EU Exchanges Interest Group of EAHN since 2017. Currently, he is a Professor of Architecture at the Pontificia Universidad Católica de Chile's School of Architecture.

MODERN FUTURES

THE ROLE OF TECHNOLOGIES IN THE MODERN MOVEMENT AND IN THE FUTURE OF DOCOMOMO INTERNATIONAL

UTA POTTGIESSER

The essay reflects on the profound influence of technology and technological advancements on architecture in the early 20th century and the 21st centuries-using. The observation starts in 1922, the year of Reyner Banham's birth, and one year before the first publication of Le Corbusier's book *Vers une architecture*, and ends in 2022. In this esssay, I took the opportunity to challenge the dominating technology of the 21st century —Artificial Intelligence (AI)— to elaborate on the future of Docomomo and to formulate recommendations.

Le Corbusier's influential book *Vers une architecture*[1], published in 1923, was a pivotal moment for architectural thinking in relation to technology. He called for a radical redesign of buildings influenced by the technological advances of the industrial age. At the center of his principles were efficiency and functionality (buildings should be like machines, serving practical purposes with efficiency), modern materials, (steel, concrete, and glass were favored for enabling new forms and designs impossible with traditional materials), and Functionalism (eesthetic considerations were secondary to a building's practical function, promoting streamlined, clean forms). The principles of the Modern Movement —functionalism, simplicity, and efficiency and social innovation— remained at the core of the architectural practice in the post-war period as a reaction to the huge challenges of the post-war housing crisis and economically growing nation-states in Europe.

In his 1960 book *Theory and Design in the First Machine Age*, Reyner Banham analyzed the relationship between technology and architecture, identifying two key periods of the first and the second machine age. In the first machine age (early 20th century), architects were inspired by industrial technology, leading to standardization and efficiency in construction. The era's optimism led to utopian designs such as Ludwig Hilbersheimers High-Rise City (1924) or Le Corbusier's Ville Contemporaine (1925) or Ville Radieuse (1933).

The second machine age (post-WWII) technology became integrated into daily life, influencing architectural features like climate control systems, mechanization, and electronics. Banham saw architecture and technology as deeply intertwined, with architecture continuously responding to and being inspired by technological advancements in different ways across these two eras. Again architects, such as Archigram's Plug-In City (1963-66), envisioned futuristic designs with adaptable, dynamic cities.

Banham critiqued modernism for not fully exploring the potential of new technologies, arguing that while modern architects spoke about technology, they often clung to formal aesthetic traditions. He praised movements like Brutalism and High-Tech architecture of the 1960s, which embraced technology's full possibilities, but at the same time stated that "we still lack a corresponding theoretical system for our own Machine Age, and we are therefore still working rather unsystematically with the ideas and aesthetic concepts that we have adopted from the First Machine Age."[2]

In 2022, Docomomo International moved its headquarters to TU Delft, a century after the beginnings of the Modern Movement. This shift marks a new chapter in the organization's mission to conserve modern architecture, focussing on digitization and digitalization in documentation and conservation processes and enhancing its advocacy for modern architecture as part of cultural landscapes. The advent of digital technologies should allow us to push this vision even further.

VISIONS ON TECHNOLOGY FOR THE FUTURE OF DOCOMOMO INTERNATIONAL[3] (FORMULATED BY AI)

As we look to the future of Docomomo International, it is important to assess the organization's current achievements, challenges, and opportunities in a rapidly evolving architectural and cultural landscape. With the advent of advanced technologies, Docomomo International is poised to enhance its mission and expand its global

---

1. Le Corbusier. 1922 *Ausblick auf eine Architektur (Bauwelt Fundamente 2)*. [*Vers une architecture*] (Braunschweig, Germany: Vieweg, 1982).

2. Banham, Reyner. *Die Revolution der Architektur. Theorie und Gestaltung im ersten Maschinenzeitalter* [*Theory and Design in the First Machine Age*] (Reinbek bei Hamburg, Germany: Rowohlts deutsche Enzyklopädie Band 209/210, 1964), 279. Author's translation.

3. This text was partly generated by using AI ChatGPT.

impact. Technologies such as digital archives, 3D scanning, virtual reality (VR), artificial intelligence (AI), and collaborative platforms can revolutionize how Docomomo operates, improving documentation, conservation efforts, and public engagement.

Traditionally, this documentation relied heavily on physical records, photographs, and printed materials. However, digital archives and databases offer significant improvements in how this data is collected, stored, and accessed. By creating a comprehensive, globally accessible digital archive of moden architecture, Docomomo can provide members, researchers, and enthusiasts with seamless access to valuable information—ideally in the spirit of open source and citizen science. Digital archives could foster collaboration among architects, historians, and preservationists from different countries. By sharing resources in real-time, local chapters can contribute to a global database, enabling a more inclusive and diverse representation of modern heritage. Incorporating metadata tagging and AI-powered search capabilities within digital archives allows users to find specific information more efficiently, ensuring that Docomomo's vast documentation is easy to navigate and explore.

Docomomo International will likely see significant changes and advancements in the tools and techniques available for the conservation of modern architecture. The increased use of digital tools like 3D laser scanning, Building Information Modeling (BIM), and photogrammetry to create detailed, accurate digital replicas of buildings. 3D scanning technologies allow for the precise documentation of existing buildings, capturing intricate details and structural nuances that traditional methods might miss. Virtual Conservation (Management) Plans based on BIM can integrate design, construction, and operational data into a single model, providing a comprehensive view of a building's life cycle.

AI technologies have the potential to revolutionize research and analysis within Docomomo International, offering powerful tools for understanding architectural patterns, predicting conservation needs, and supporting historical studies. AI can analyze large datasets to identify common architectural features, stylistic trends, and regional variations. This data-driven approach allows for a deeper understanding of the Modern Movement and can help researchers uncover previously unnoticed connections between architects and design philosophies. AI models can analyze the structural integrity of buildings, predict potential areas of decay, and recommend conservation efforts. AI-powered algorithms can sift through vast amounts of historical documents, archives, and blueprints to extract relevant information quickly.

New advancements in materials science, sustainable materials and techniques, such as self-healing concrete, improved insulation technologies, and sustainable retrofitting techniques, will likely play a critical role in preserving these structures while addressing contemporary sustainability concerns.

As virtual and augmented reality (VR/AR) become more sophisticated, Docomomo could expand its outreach and education efforts by using these technologies to create immersive experiences. Engaging the public and educating them about modern architecture is essential for raising awareness and fostering appreciation for Docomomo's mission. Both technologies offer immersive ways to bring modern architecture to life for broader audiences. AR can provide enhanced on-site experiences. By using AR-enabled devices or smartphones, visitors can see overlays of original architectural designs, receive historical information, and visualize how buildings have evolved over time. This technology can turn any visit into an interactive, educational experience.

In an increasingly connected world, digital platforms that facilitate global collaboration are crucial for the organization's future success as is community engagement and social relevance. Conservation efforts must also take into account the communities who live in or around modern buildings. Docomomo will need to engage more directly with these communities to ensure that their needs and perspectives are included in preservation decisions. This is particularly important for modern housing estates, many of which have been criticized for fostering social isolation. Ensuring that these buildings are maintained in a way that serves the needs of current residents will be a key challenge moving forward.

DIGITIZATION, DIGITALIZATION AND SUSTAINABILITY

The future of Docomomo International presents both significant opportunities and challenges in its mission to preserve modern architecture. As technological innovations, cultural shifts, and environmental concerns reshape the landscape of architectural conservation, Docomomo must embrace adaptation and innovation. By leveraging digital tools, promoting sustainable preservation, and fostering greater inclusivity and diversity, the organization can maintain its leadership in the conservation of modern architecture for decades to come.

As urbanization intensifies and architectural values evolve, Docomomo's role in safeguarding the legacy of the Modern Movement will grow even more crucial. Strategic collaborations, sustained advocacy, and a commitment to inclusive conservation will ensure that modern architecture remains a vibrant, relevant part of our shared cultural

heritage. Technologies like digital archives, 3D scanning, VR/AR, AI, and collaborative platforms will play a pivotal role in the future of Docomomo International. These tools not only enhance documentation and conservation efforts but also engage the public in innovative ways, ensuring that the modern architectural heritage is preserved for future generations. As Docomomo leverages these technologies, it will be better equipped to protect, document, and celebrate the legacy of the Modern Movement, expanding its impact on a global scale.

In many ways, the current focus on digitization, digitalization and sustainability is a continuation of the Modern Movement's original mission of social progress. Just as early 20th-century architects used emerging technologies to improve living conditions and promote social equality, today's architects should employ digital innovations to address the pressing challenges of climate change and resource depletion. Reinstalling architecture and urban planning as relevant, holistic disciplines in academia and practice requires embedding sustainability, resilience, and inclusivity into their very foundations. Through interdisciplinary collaboration, technological integration, community-centered planning, and policy reform, architects and urban planners can lead the charge in creating cities and environments that are not only sustainable but also equitable and adaptable to future challenges. This is essential for ensuring the long-term health of our built environment and society—as it was in Modern Movement.

Uta Pottgiesser is an architect and Professor of Building Construction and Materials at Technische Hochschule Ostwestfalen-Lippe (TH OWL) in Germany and Professor of Heritage & Technology at TU Delft, the Netherlands. She is a board member of Docomomo Germany and has held various functions at Docomomo International since 2008, in particular as Secretary and Chair of the International Specialist Committee on Technology (ISC/T) from 2014–2021. Since 2022, she has been Chair of Docomomo International. In that capacity and as editor of the Docomomo Journal, she is concerned with the protection, reuse and rehabilitation of modern built heritage and promotes advanced technologies to document, visualise and plan interventions to existing buildings. She has published key papers and several books, among them Reglazing Modernism. Intervention Strategies for 20th-Century Icons (Birkhäuser, 2019), awarded with the 2021 Lee Nelson Book Award from the Association for Preservation Technology International (APT).

THE ROLE OF MODERN ARCHITECTURE IN SHAPING TOMORROW

ANA TOSTÕES

Modernism is the defining architectural conception of the 20th century, a movement that transformed the built environment around the world in an unprecedented way. When pioneering architects first explore the symbiosis between new ways of living and emerging construction possibilities, they paved the way for contemporary architecture, guided by visionary concepts of form, space, technology, and social responsibility.[1] Modern Movement architecture embraced contemporary technology, expression, and, most importantly, the belief that the architect's social mission was to create a new and better world. It became a vehicle for social change, promoting collective aspirations and ambitions. As part of a global synthesis process, modern architecture had to adapt to specific contexts, allowing the identities of different places and cultures, as well as geographical regions and peoples, to become visible in their subtle diversity.

Today, more than 100 years have passed since the first built manifestations of the Modern Movement. Some values have been reassessed, adapted, or even rejected. Nevertheless, its founding spirit, intrinsically tied to the foundation of contemporary society, remains valid and, one could argue, is still evolving. After a period of significant unpopularity, the values of the Modern Movement have been rediscovered and are being put into practice by new generations of architects who are re-exploring the path of a reawakened modern architecture, learning from it and creating something new.[2] The principles of the Bauhaus continue to be relevant, with "the great issues of sustainability and democracy needing to be addressed through art and technology."[3]

With an optimistic faith in progress, modern architects aimed to achieve new heights in beauty, functionality, and flexibility of use. Today, as the original functions of many of these buildings are no longer required, or they face urgent repair needs, the challenge lies in addressing this modern legacy within a continuously evolving context. This includes physical, economic, and functional changes, occurring against an ever-shifting backdrop of sociocultural, political, climatic, geographic, and scientific factors.

Modernity has come to be recognized as world heritage and is now perceived "as a sustainable design tool, a project method, and finally, as being crucial to the future of architectural production and cultural debates."[4] Issues such as the reuse of materials and technology, spatial and functional transformations, and updating legislation, are increasingly becoming central to the contemporary agenda. Currently, its most pressing mission is the pursuit of a sustainable future.[5] Along with restoration and conservation, renovation and adaptative reuse are starting to "make history," embracing the concept that heritage transforms itself with us.[6]

To preserve the architectural heritage of the 20th century, we must recognize both the opportunity and obligation to reuse buildings that have lost their original function, are physically or technically obsolete, or no longer meet today's increasingly stringent standards. Subjects such as physical restoration, the need for spatial or functional transformation, and ensuring contemporary comfort and safety requirements within a framework of environmental sustainability are central to current discussions. This inevitably raises questions about the value of existing structures, which, while a valuable resource, require careful consideration of social, economic and environmental sustainability. Thus, intervention strategies are, in many ways, an artistic judgment that demands a deep understanding of a building's design history, a careful assessment of the materials and techniques used in its construction, and a thorough knowledge of its life and uses.[7]

Architectural preservation is a discursive practice that seeks legitimacy, not only by drawing on history, but also, and perhaps more importantly, on collective memory.[8] In this context, it is essential to remember that the collective memory and involvement of local inhabitants are crucial in keeping this modern heritage alive. Memory plays a significant role, not only in preserving monuments of modern architecture, but also in recording the oral histories of everyday life,[9] such as the experience of children happily exploring and playing within these spaces, with their promise of adventure and innocence. This was captured by Ernesto Nathan Rogers during a critical moment of Modern Movement architecture as "*la sperienza del architettura*."[10] The expansion process of information sources allows, in Juhani Pallasmaa's words, to admit that buildings not only provide shelter and sensory pleasure, they "are also mental extensions and projections, they are externalizations of our imagination, memory and conceptual capacities."[11] The raises the challenge of how to maintain the intensity and emotional impact of architecture when it becomes necessary to intervene in its materiality to renew and adapt it to the contemporary needs. In such cases, we must heed Wessel de Jonge's reminder "that our practice is informed by a historical consciousness and sensibility that goes beyond purely formal or technical dimensions."[12] Beyond economic considerations, the adaptive reuse of modern buildings continues to be recognized for its ability to enhance critical issues of identity and contribute to the sustainable life of buildings. As Pallasmaa highlights, "cultural identity, a sense of rootedness and belonging is an irreplaceable ground of our very humanity."[13]

While addressing the concept of reuse as a key factor in building a sustainable future, one must recall the Modern Movement's social commitment, which, for the first time, tackled the challenge of housing for the masses. It promoted an architecture that could provide not only provide a decent home for all,[14] but also the promise of a healthy life grounded in comfort and well-being.[15] In other words, it envisioned architecture as a decisive factor in the pursuit of happiness[16]; one of the Modern Movement's core themes was architecture as a tool for creating a new, egalitarian society. As Walter Gropius envisioned, architecture serves as an agent of civilization that helps "suppress the chasm between reality and ideology,"[17] positioning the architect as a professional who makes choices and seeks solutions, an instrument for a better society.[18] The architect is not merely a passive participant in progress but an active agent capable of influencing collective conscience and, in turn, guiding the process of progress. Today, architects carry the duty and power to preserve the legacy of modern architecture.

Hubert-Jan Henket's question "for those who are dedicated to the ideas of the Modern Movement, this attitude shouldn't come as a surprise. Isn't one of the driving forces of Modernity, ever since the Enlightenment, the dedication to dynamism and the constant new?"[19] points to the essence of any thoughtful modern-heritage reuse project. Any transformation must honour the original architect's intentions, maintaining a balance with the cultural significance of these intentions while enhancing the overall architectural quality. Furthermore, reuse, renovation, and restoration

not only raise technical issues regarding materiality and physical obsolescence, but also provoke deeper conceptual considerations about the fundamental nature of buildings.

If Docomomo's initials stand for the documentation and conservation of buildings, sites and neighbourhoods of the Modern Movement, then we need to go beyond the practical cases of conservation and explore the documentational and theoretical aspects of Docomomo's mission. Despite the urgent and unprecedented environmental and climate challenges facing humanity, as well as a global pandemic that has shaken confidence in a peaceful, science-driven future, architecture remains optimistic about the future and about the creative potential of architects to meet the world's forthcoming demands.

History and life are two intertwining concepts embedded in our contemporary understanding of modern architecture. On the one hand, modern architecture has earned its rightful place in history; on the other, it is not a frozen relic. It continues to serve as the shelter for our daily lives and as the inspiration for the habitats of the future.

Ana Tostões is an architect, architecture critic, and historian. Full Professor at Técnico – University of Lisbon, where she serves as the Chair of the Architecture Scientific Board and is responsible for the PhD program. She is the leader of the Heritage research line at the Center for Innovation in Territory, Urbanism, and Architecture (CITUA). She has been invited professor at the University of Tokyo, the University of Navarra, FAUP, and KU Leuven, among others. She was the President of Docomomo International and the Editor of the *Docomomo Journal* (2010-2021). She has authored books and essays, curated exhibitions, participated in juries, scientific committees and delivered lectures at universities worldwide. She is president of the Portuguese section of AICA. She was awarded the X BIAU Prize 2016 and distinguished with the Commander degree of the Order of Infante Dom Henrique and in 2024 with the *Médaille de la critique et des publications* by Académie d'Architecture.

DOCOMOMO. THEN, NOW, AND THE FUTURE

MARISTELLA CASCIATO

"*It is necessary to consider the past a historical present …and to forge another 'true' present*" — Lina Bo Bardi[1]

It was April 1989 when Italian architect Lina Bo, married Bardi, was addressing her speech to a small group of guests gathered together at the opening of her first retrospective exhibition, held at the University of São Paulo. She was then seventy five years old.

That same year, in November, the Berlin Wall was destroyed, ending the geo- political Cold War and creating the conditions for the collapse of the Soviet Union. It seemed that the tombstone of a dreadful past was laid down for ever; no route back to previous histories and an atmosphere of optimism.

Nowadays, reconsidering Bo Bardi's words, one also captures in her acknowledgement a kind of renewed optimism, in which the "now" is the "true" turning point. Doubtlessly, she was not alone in her awareness and confidence in the values related to architecture and to its global legacy in the broadest terms.

Now, it is my chance to look backward, to one year earlier, to the Fall of 1988; it may sound to be a coincidence, though it is not.

At the School of Architecture, University of Eindhoven, Dutch architect Hubert-Jan Henket, himself an optimist by nature, had gathered a number of local and international colleagues to launch a crusade aimed to foster the belief in the reconciliation of the cultural and social virtues of what was built under the banner of modernity, and the appraisal of its economic success.[2]

The acronym Docomomo (Documentation and Conservation of the Buildings, Neighborhoods and Landscapes of the Modern Movement) which designated the new organization, arose from a few days of intense confrontations;[3] it remained obscure for the many and for several years ahead, though it finally became effective in giving voice to an amalgam of visions, hopes, and utopias which were clearly kept in standby. In the year 2000, I began my tenure as international chair which lasted ten years.

Most recently, Horacio Torrent, chair of the conference to be hosted in Santiago de Chile in December 2024, approached me aiming for a critical, fresh reconsideration of the future of Docomomo.

His call surprised me. Which future was he considering? The future we envisioned then, at the end of the '80s, the futuristic past or the "future anterior," to echo the oxymoronic title of a successful magazine. The *hic et nunc* future or the future for perpetuity? Torrent's quest left me with a handful of uncertainties. It definitively opened a Pandora box.

Back from Utopia, the book that came out in 2002 celebrating the first decennia of Docomomo, brought up to date the spirit of the beginnings of the organization and created a shared ground, an encounter between masters (those still alive and those idealized) and young, motivated professionals. This publication remains for me a keystone, therefore I went back to dive into it and adopted it as a device for mapping my own responses about the "now," carefully avoiding any nostalgia for the past and any lure for future.

The forty five contributors to *Back from Utopia* were tight to a mission and to an ethos which proved to be professionally transformative and intellectually engaging; they promoted a very fruitful new wave and new knowledge in the field of architectural conservation. The concerns initially expressed by Henket seemed to have found enthusiastic accolades. "A new spirit" —*Un Esprit Nouveau*, he wrote rehearsing Le Corbusier's generative idea— "a new dynamism, and an integrated effort of science, technologies, and arts" was born[4]

In her coda to the book, historian Hilde Heynen set the tone for what could become my current assessment. Let's begin from the acronym —Docomomo— which intended to endorse and to foster the legacy of the modern

3. About Docomomo, see: *The Modern Movement in Architecture: Selection from the DOCOMOMO Registers*. Dennis Sharp & Catherine Cooke eds. (Rotterdam: 010 Publishers, 2000).

4. Henket, "Back from Utopia…," 17.

heritage. The *where* and the *when* of that project were never put under scrutiny, nor any critical questioning of the *whose* legacy ever surfaced. Though in her essay Heynen discussed at length the constituencies of the modern discourse, borne from the cradle of the avantgardes, and examined the limitations embedded in the vision of the modern movement, the hegemonic power of the Eurocentric thinking and practicing remained unchallenged.

Today, at the dawn of the second quarter of the twentieth-first century, the neo- liberal drift of the postcapitalist societies and the encounter with the global histories of the postcolonial and decolonized nations call to think at architecture through frames of pursuits, and to "reflect the compulsion to advance the cause of a more accurate, just, and inclusive historiographic practice."[5]

What I argue is that the most advanced agency for sustainable programs should stay free from patronizing and grew out of learning from partnership; in the end, this requires the endorsement of new traditions and the return to craft.

In this perspective it is now time to exchange knowledge, to sustain the relevance of a new humanism, to foster changes in the professional fields, and to consider questions of technological capacities in a global approach to one of the pillars of Docomomo, the world of archives and documentation of sources.

In conclusion, I wish to touch upon a re-examination of the significance and evidence of the archive, and on the urgency of building a new knowledge that overcomes the conventional agenda of the archive as neutral depository. My aim is to engender a more expansive approach to the archives, on one side committed to the interdisciplinary nature of the art of building (materials, data, manuals, etc.) and to the intersectionality of the methods of designing and curating (models, robots, 3D scanning, AI and AR platforms, etc.), and on the other side orienting their physical exploration as object entangled in the subjectivity of the virtual narrative.
Consequently, I suggest the establishment of a diagram of practices and cultural structures, encouraging a conversation in which the architectural discipline is embedded.[6]

a. **What** does constitute the archive within the boundaries of the global, multi- and interdisciplinary professional practice?
b. **When** does the design ethos of the past merge with the more current challenges?
c. **How** do we interpret the specificity of the materials and the tools used in the design and construction apparatus in creating the archive?
d. **Where** does stand the physical space/building of the archive vis a vis the original power structures of the design(er)?
e. **Why** are architecture records held? Among the obvious responses, one can list memory, context, identity, legacy, etc. To some extent, Jacques Derrida's *Archive Fever* offers a definitive assessment to this query.[7]
f. **Who** are the custodians —authors, collectors, institutions— of the archives?

Los Angeles, Summer 2024

Maristella Casciato (architectural historian and educator) is senior curator of architectural collections at the Getty Research Institute in Los Angeles. She was a tenured associate professor of history of architecture at the University of Bologna, School of Architecture from 2002-2012. She was awarded a Fulbright Fellowship (1992), a research grant at the INHA in Paris (2004), and the Mellon Senior Fellowship at the Canadian Centre for Architecture in Montreal (2010). She was Chair of Docomomo International 2002 - 2010. She has been nominated 2023 Fellow of the Society of Architectural Historians.

7. Read Derrida's inspiring opening note in *Archive Fever. A Freudian Impression* (Chicago: The University of Chicago Press, 1995), 1: "Let us not begin at the beginning, nor even at the archive.
But rather at the word 'archive'—and with the archive of so familiar a word. *Arkhé* we recall, names at once the *commencement* and the *commandment*. This name apparently coordinates two principles in one: the principle according to nature or history, *there* where things *commence* —physical, historical, or ontological principle— but also the principle according to the law, *there* where men and gods *command*, there where authority, social order are exercised, *in this place* from which *order* given- nomological principle. *There*, we said, and *in this place*. How are we to think of *there*? And this *taking place* or this *having a place* of the *arkhé*?"

REVALUING DOCOMOMO

HUBERT-JAN HENKET

THE MODERN MOVEMENT OUTDATED?

Many critics claim that the Modern Movement is an outdated phenomenon of the 20th century. I do not agree at all. The intention of the Modern Movement is more relevant than ever before. That intention is to create a better world for everybody, that means nobody excluded, through the implementation of innovative progress in culture science and technology. However, the conditions to reach this goal have dramatically changed. To paraphrase Cedric Price: Technology, science and culture are the answers, but what are the questions?

Due to out-of-control rationalization, fragmentation, productivity and scale maximalization, communication acceleration and a free for all marked economy, we are forced to drastically change our direction. The questions for today and for long after tomorrow are how to organize controllable technology, how to cope with climate change, energy neutrality, pollution, limited resources, decline in biodiversity, social cohesion etc. We are beginning to comprehend that we should stop dictating nature, nature is dictating us. As Mahatma Gandi warned us long ago, nature can provide everybody with sufficient food, but it cannot satisfy the greed of mankind.

An enormous task lays in front of us architects and planners to reunite ourselves with nature and rehumanize our built and unbuilt environments with sustainability as our global ethic. In other words, stop short term thinking, stop pollution, destruction and depletion. Embrace the long term, balance reason and emotion, reuse all qualities of the existing and realize this collective task through meaningful citizen participation. Welcome to the dynamic reality of a sustainable Modern Movement 2.0.

SUSTAINABLE CITIES, BUILDINGS AND LANDSCAPES

Cities first and foremost exist to satisfy the social needs of communities. Yet the necessary feeling of involvement, inclusion and security are eroding ever more. Today's world does not consist of one whole but a myriad of big and small groups with different origins and backgrounds. So, we are confronted with the growing needs of pluralistic demand. Yet all these groups and individuals can only be themselves if they get the possibility to feel at home, a place where they don't have to defend their convictions.

We should learn again that care creates trust, and that trust creates wellbeing and pride. These two are preconditions for renewing our environments with things that are there already. Environments where the old and new meet in harmony. Don't forget: "small is beautiful".

My teacher Aldo van Eyck always emphasized the key role the social and public realm play in any society and the necessity to recover their symbolism. Man communicates through language, gestures and form. These give information about the meaning system that we as a social group have developed, maintain and want to further. This dynamic system has two sides. On the one hand we experience fear and resistance to lose that what makes the identity we are used to. We love a sense of memory. On the other hand, there is the need to cope with continuous change and to accommodate the new in our search for progress.

To help the different individuals in a group feel at home, and outsiders to join, this meaning system should be as neutral as possible. Equally important are beauty, respect and therefore love for our buildings and neighborhoods, three essential ingredients for their appreciation in the social group and their longevity as desired companions. In search for a balance between the competing forces neutrality and unicity, creative imagination is one of the main conditions for anyone involved in construction and transformation.

We are assisted in this emotional endeavor by rational, technical, environmental and cost efficiency facts. Existing buildings and infrastructures normally have a built-in technical lifespan of at least 100 years just to meet structural safety requirements. When you add to this the energy embedded in the huge existing stock, then it makes perfect sense to reuse all that exists as much as possible for the development of a sustainable social future.

Besides, consider a few more aspects. To comply with energy efficiency and to neutralize our carbon footprint, to respond to long periods of drought and heavy rainfall and to create heat reduction we should change our ideas about the city plan. In future it should consist of green self-supporting yet integrated mini cities with a walking radius of say 15 minutes. They must be provided with the necessary public facilities, parks, bicycle lanes, efficient public transport, rainwater storage, vegetable gardens and meeting places of different scales.

As the key to managing the existing stock and new construction, our thinking should be based on the lifecycle of buildings and infrastructures. In other words, long-term structural life, renewable materials plus the demountabilty and reuse of components.

Landscapers should concentrate on the repair of natural order, in search of a renewed relationship between nature and culture. Not only the increase in financial value should be a driving force, but the capacity of the soil and the recreative quality of the landscape as well. Beauty, health and social wellbeing are vital factors for a humanized economy.

To achieve this, social cohesion and participation are essential. The approach should be "Not me and now, but we and our future." This will help to bring all stakeholders i.e. citizens, owners, developers, professionals, business and government together to form new partnerships. Fruitful consultation and discussion are only possible when all parties involved are prepared to ban extremism. After all, absolute ideas run the risk of becoming so unchanging that individual human intention is crushed in the subservience to the totality. Every stakeholder has its own interest, vision and input to reach the communal goals. The trick is to be able to respect each other, be prepared to compromise and appreciate the ironic.

CODOMOMO?

It is precisely in this context that the Docomomo network can form an important connection between vision and reality in the global effort to arrive at a sustainable future. Why?

Since 1990 we have shown, through output and presence, to be an accountable international organization, consisting of architects and planners both practicing or academics and architectural historians, operating in a large network of 78 national or regional working parties and five International Specialist Committees. Our mental guide is the Eindhoven-Seoul Statement.

In the last century more has been built worldwide under the banner of Modernity than the production of all previous centuries added together. We already know quite a bit about this huge building stock, and we could enlarge this knowledge considerably. Did we concentrate in the first years of our existence on the icons, later we moved to the sub-icons as well. In Rotterdam in 2008 we started discussions about sustainability, and in Seoul in 2016 we introduced the Eindhoven-Seoul Statement in which adaptive reuse and sustainability were added to our joint effort. The ISC on technology has produced an impressive number of informative dossiers on the conservation of modern materials and components.

The ISC on Registers and the *Docomomo Journal* have introduced us to the knowledge of the icons and sub-icons worldwide via documentation. Many case studies presented at conferences have broadened that knowledge. But a funny thing has happened since we started. When we were discussing an appropriate name for our initiative in 1988, we decided to put documentation in front of conservation, mainly because of the common negative appreciation of MOMO architecture and planning back then. We reasoned, documenting was a more effective way to save culturally interesting buildings and neighborhoods which were designed for a relative short functional lifespan. Conservation should be reserved for the cultural happy few. Today we have a totally different point of view. Now the sustainable conservation of both icons as well as the bulk of the ordinary are at stake, in various degrees of intervention. So today the abbreviation "CODOMOMO" would have been more appropriate.

FUTURE CHALLENGES

The question then is, how should we approach these challenges that match our character. Experience tells us that we should not try to expend our range of tasks too much, simply because we are a voluntary organization and because we don't want to fall in the bureaucracy trap. Besides, our network of working parties varies considerably due to different cultures, habits and circumstances.

- So rather than expend, my proposal is to strive for more efficiency and to focus on specific items within agreed timeslots.
- Make a long-term plan of action over a 10-year period, accommodating biannual tasks of homework for all working parties, in descending order of urgency. Give the ISCs, closest involved in a given subject, a guiding function.
- Put more effort in reactivating dormant working parties. We need everybody's input.
- Change our documentation effort from registers to informative case studies including both positive and negative experiences, according to a well-designed standard framework. We desperately need this practical information to convince non-believers that adaptive reuse of MOMO buildings and neighborhoods is worth their while.

- Stimulate all working parties to put more effort in enlarging contacts with communities, owners, developers and politicians by using the practical new case studies. And ask them to approach the media to inform citizens about the advantages of conservation of the largest part of their building stock for the sustainability task ahead.
- Stimulate closer cooperation with international organizations with similar goals.
- Education, education, education.
- Stimulate architectural historians to analyze and describe the cultural key factors of common MOMO buildings and neighborhoods of a particular period in their country. This helps architects and planners to redesign sustainable buildings and city plans.
- Stimulate architects, planners and architecture schools to stop sectoral thinking and use the complete lifecycle of objects as the integrated guiding principal. So together we can offer knowledge of conservation matters as an integral part of asset management.
- Gather information on the technical and functional life expectancy of conservation interventions and make it useful for specific areas in the world.
- Read the recent excellent book by John Allen *Revaluing Modern Architecture*. For non-British students and professionals most of its content is very informative.
- Keep enjoying the friendships in our Docomomo community. They will continue to be our most precious condition for our future contribution to better the planet for everyone!

August 20, 2024

Hubert-Jan Henket (1940) qualified *cum laude* as an architect at the Delft University of Technology. He worked for Aldo van Eyck, studied in Helsinki and worked for Reima Pietala and worked in London for the Housing Renewal Unit. In 1976 he founded his practice in the Netherlands, since 2010 known as BiermanHenket architects. He is emeritus professor of the Eindhoven and Delft Universities of Technology and co-founder as well as honorary president of Docomomo international.
He concentrates on the relationship between old and new. He was involved in the restauration of buildings by Berlage, Dudok, Rietveld, Duiker and Max Berg. He designed transformations and new museums, law court buildings and the Dutch Embassy in Bangkok. His pavilion for museum Boijmans van Beuningen in Rotterdam (1991) was recently added to the list of national monuments of the Netherlands. His latest work was the renovation of the royal palace Huis ten Bosch in the Hague. With Hilde Heijnen he edited the book *Back from Utopia* (010 Publishers, 2002). He received several national and international awards, such as the World Monuments Fund, Knoll Modernism prize for the restauration of Sanatorium Zonnestraal in the Netherlands together with Wessel de Jonge.

SUSTAINABLE DEVELOPMENT

ORIGINAL DESIGN INTENT, LAYERS OF HISTORY AND THE NEED FOR ADAPTATION TO A CHANGING WORLD

SCOTT ROBERTSON
DIRECTOR, ROBERTSON & HINDMARSH PTY LTD, ARCHITECTS

ABSTRACT

The Docomomo Eindhoven-Seoul Statement (2014) embodies aspiration that Modern Movement buildings can be adaptively re-used to both conserve the significance of the buildings and to extend their useful lives either beyond their original "use-by date" and/or beyond their original use. Often, however, the option of adaptively re-using a building is not adequately assessed in that the embodied energy, emissions and carbon of the existing structure are not accounted for in the feasibility for future options and neither is the full-lifecycle of the use of the existing or the proposed building assessed in terms of the emissions of occupation and the emissions involved in the demolition of the existing building.

Adaptive re-use often entails the total transformation of the building so that it is no longer the original building, even when the adaptive re-use is undertaken to maintain the original function, such as the thermal upgrading of an existing high-rise apartment building. The situation is even more complicated when the adaptive re-use is for the conversion of a building to a different use, such as the conversion of an office building into a residential building.

However, adaptive re-use need not require the loss of significance, especially if the significance of the building is adequately recognised and stated in a document such as a conservation management plan and the design intent of the original architect is respected and enhanced.

1. INTRODUCTION

The need to upgrade buildings so their existing use remains viable or to adaptively re-use them for another use generates a conversation regarding conserving their significance and ensuring their utility and survival into the future through compliance with current codes surrounding matters such as energy consumption, thermal comfort, and accessibility.

International charters such as the Venice Charter (1964) and national charters such as the Australia ICOMOS Burra Charter (1979, 2013) emphasize the retention of the layers of history as represented by the original physical fabric and accretions of physical fabric over time. Whilst such an approach may be applicable to international monuments that are preserved as static ruins, it is more difficult to apply to buildings and sites that are continuing as integral functional elements of current society. An example would be the Sydney Opera House which, despite being a recent construction and the youngest place inscribed on the World Heritage List, has undergone an extensive program of renewal to maintain its environmental and functional efficiency as one of the world's busiest performing arts complexes, including providing wheelchair access to parts of the building that have never before been accessible.

The Docomomo Eindhoven-Seoul Statement (2014) embodies this conversation and conflict within its wording in that it promotes the conservation and adaptive re-use of Modern Movement buildings and sites whilst opposing the disfigurement of significant works. How much change can be tolerated to a significant work to retain its efficient functioning without a loss of significance?

The Sydney Opera House is a special case in that its World significance has enabled a thorough process of examining and respecting the building's significance, down to the smallest elements in an award-winning Conservation Management Plan.[1] However, most government, commercial and private projects do not benefit from such a comprehensive assessment of significance and often come from a pre-judged position of downplaying or even denigrating the building's significance in order to justify demolition and redevelopment.

2. PRESSURES FOR REDEVELOPMENT

Mid-twentieth century Modern Movement buildings are under increasing threat of demolition for a number of reasons; original use no longer economically viable within the constraints of the current building, modern standards of space requirements not being met, current environmental standards not being met, accessibility or building regulation standards not being met, image and prestige requiring a "new" image, and political reasons (such as removal of social housing complexes from desirable areas), etc. These threats apply to all types of post-war buildings ranging from the simple, post-war single-family bungalow, to high-rise office blocks and residential blocks.

Population increase and the rapidly increasing cost of housing are bringing many pressures to bear on the conservation of important buildings

1. Croker, Alan, *Respecting the Vision: Sydney Opera House – a Conservation Management Plan* (Fourth Edition), 2017, accessed June 2024, https://sydneyoperahouse.com. The CMP was one of the Lasting Heritage award winners in the inaugural Docomomo International Rehabilitation Awards in 2021.

of the twentieth century. Increasingly, conservation of the past is being represented as an impediment for an up-scaling of residential densities and conflicts are now arising between those who want to preserve the urban and suburban character of their cities and those who need to increase an affordable housing supply to accommodate an increasing population as well as to introduce modern infrastructure.

Post-war high-rise office buildings pose a particular problem in that they are usually located in prime locations with sweeping views of natural features such as harbours or rivers and are located close to public transport hubs. In cities with geographical constraints there is greater pressure to increase height and density to maintain a competitive edge in commercial office space rentals. This is becoming even more pronounced in a post-Pandemic environment as many workers shun the city office and work from home either full-time or part-time.

Two office building examples resulting from declining office usage and the need to adaptively re-use the buildings are the former MLC office building in Sydney, Australia and the former Republic National Bank building complex in Dallas, USA.

3. RETENTION OF OFFICE BUILDING SIGNIFICANCE

3.1. FORMER MLC OFFICE BUILDING, SYDNEY, NSW, AUSTRALIA: DEMOLISH, UPGRADE OR ADAPT?

An example of a mid-century high-rise office building under threat is the former MLC Building at North Sydney located just north of Sydney Harbour (**Fig. 1**). The headquarters of the MLC insurance company was designed in 1954 by architects, Bates, Smart & McCutcheon, and completed in 1957. At the time of its completion, it was the largest office building in Australia and was certainly the tallest building in the then low-rise suburb of North Sydney.

In the mid-1990s, the MLC company revitalised and upgraded the building to accommodate the changing office working environment. Floors were opened up to one another with stairs and atria, the technology of the building was upgraded, and the important aluminium and glass curtain-walls on the long east and west façades were refurbished, as were the short north and south tiled façades. This adaptive re-use won architectural awards.

In 2020 the new owners of the building, even knowing that the building was a listed heritage item, submitted a development application to demolish the building and replace it with a new office building. The building is located immediately adjacent to a new metro station that will be operational by late 2024 and so a new building could be expected to command top rental returns.

The application to demolish was eventually refused but the government-appointed Independent Planning Panel stated that the distinctive aluminium and glass curtain-wall could be removed and replicated in any refurbishment of the building. In 2023 the building was finally listed on the State Heritage Register by the newly-elected left-of-centre Labor state government as an item of State environmental heritage. However, such a high level of protection can be ephemeral and ineffective in the state of New South Wales

as the same Labor government has maintained a policy from the previous right-of-centre Liberal government that important projects, that have been declared to be State Significant Development (SSD), automatically have heritage "switched off." In other words, heritage is no longer to be taken into consideration when considering the merits of the proposed development.

Recently, the owners of the former MLC Building have indicated that they will not refurbish the building as an office building but will submit the redevelopment of the existing building into what is called "build-for-rent" apartments as a State Significant Development. Such an approach is politically timely in that there is a housing shortage in Australia and a severe rental crisis in terms of availability and affordability. This type of project is likely to appeal to the state government and its SSD status will preclude heritage considerations.

A curtain-wall façade is difficult to be compatible with opening windows that art mandated by the codes for apartment buildings. Balconies are also desirable in the temperate Sydney climate. High-rise office buildings have usually been converted to apartments by the total removal of all cladding and the reduction of the building to its concrete floors and columns. Such drastic change is not envisaged by Docomomo's Eindhoven-Seoul Statement.

One of the problems is that the true economic and environmental cost of removal of original fabric is not adequately accounted for in assessing projects. The tools for such assessment do exist but, in Australia for example, they are not mandated and there are no national standards to determine maximum thresholds of embodied emissions or carbon that can be sacrificed in a building redevelopment proposal.

However, in the absence of any embodied emissions controls, another method of encouraging retention of building fabric and, therefore, cultural significance is to incentivise retention.

3.2. FORMER REPUBLIC NATIONAL BANK BUILDING, DALLAS, USA: INCENTIVISED CONSERVATION

In Dallas, Texas there is a combined State and City tax relief of up to 45% for retaining the external appearance and major internal features of significant buildings. Encouragement of the new and respect for the recent past go hand-in-hand because Capitalism has been harnessed to provide incentive. An example is the central tower of the former Republic National Bank complex which was converted from offices to the gables Republic Tower apartments, in 2005-2007 by Corgan Associates, without impacting the striking pressed aluminium panel-clad exterior of the tower. The Republic National Bank was originally designed by Harrison & Abramovitz in 1954 (**Fig. 2**).

The building contains one-, two- and three-bedroom apartments and communal facilities such as a roof-top swimming pool.

The retention of the office building façade in the apartment conversion ensured the aesthetic significance of the building was maintained but the habitability of the building's apartments relies on air-conditioning year-round to cope with the hot summers and cold winters of Dallas as well as

to provide air changes. Such a minimal impact adaptive re-use may not be suitable or even permitted in jurisdictions where natural ventilation via openable windows and/or balconies is a requirement.

4. SOCIAL HOUSING

4.1. UPGRADING SOCIAL HOUSING BUILDINGS FOR THE RICH: SIRIUS BUILDING, SYDNEY, AUSTRALIA

With the current housing supply and affordability crisis, government decisions regarding the disposal of social housing are of great concern. The Sirius building was designed and constructed by the NSW state government between 1976 and 1980 as social housing in The Rocks overlooking Circular Quay, Sydney Harbour and the Sydney Opera House (**Fig. 3**). Sirius was constructed as part of a deal struck in the 1970s between the state government and the Building Labourers Federation (ie trade union) to lift the work bans (known as Green Bans) in the area in exchange for the building to house the local residents that were being displaced by the government-sponsored and government-controlled commercialisation of The Rocks as an entertainment and tourist precinct. The building was an important Brutalist building in an extremely prominent location that can be seen from the Opera House and from the Sydney Harbour Bridge.

Despite the Heritage Council of NSW proposing that the building be listed on the State Heritage Register, the state government refused to permit the listing in order to maintain a high price when it was sold to a private developer. The developer retained the existing building but added copper-clad modules to increase the height and number of apartments and also copper-clad hoods and balconies to some of the apartments. The building was gutted internally and posed challenges for a contemporary upgrade to comply with codes such as sound transmission between units because of the existing minimal floor to ceiling heights. In addition, the design of the new apartments involved the conversion of social housing apartments to high-end, high-luxury, and high-cost apartments in a stunning location. The building has been further gentrified by the smoothing out of the rough-sawn board formwork marks on the concrete walls. But after this renewal, the new, aesthetically pleasing building is no longer the original.

The Sirius building has been "saved" but at the cost of the loss of its original aesthetic authenticity, the loss of its social significance as public housing, and the loss of its historical significance as social housing to accommodate the displaced local residents. Its retention as housing has done nothing to alleviate the lack of affordable housing and has displaced and dispersed residents, some of whose families had lived in the area for over 120 years.

4.2 UPGRADING SOCIAL HOUSING BUILDINGS FOR WHOM? PUBLIC HOUSING TOWERS, MELBOURNE, AUSTRALIA

Like its NSW counterpart, the Victorian state government is intending to decant social housing tenants from 44 high-rise towers dispersed throughout Melbourne and demolish them in order to redevelop the areas for a mix

of social, affordable and market-price housing. However, an alternative approach of retaining and refurbishing social housing has been shown to be successful as demonstrated by the Melbourne-based OFFICE, a charitable not-for-profit design and research practice, who produced a report on development options for one Melbourne public housing estate, the Barak Beacon Estate. The report emphasised that OFFICE's Retain Repair Reinvest (RRR) approach of retaining existing communities, repairing existing buildings to reduce environmental impacts of construction, and reinvest the savings to improve comfort and to upgrade public housing.[2] The report established that the RRR model provided a 25% increase in site occupancy, retained the existing community, saved the government the cost of relocating and rehousing the existing community and, compared with the demolish and rebuild strategy, the RRR strategy provided a 54% reduction in embodied energy and 46% reduction in global warming potential.

In March 2024 OFFICE produced a further report, *Life-Cycle Impacts of Public Housing in Victoria*, that examined different social housing renewal strategies and their environmental and social impacts for the entire government social housing portfolio in Melbourne.[3] The report emphasised the use of a Life-Cycle Approach of cradle-to-cradle (as contained within European life-cycle Standard EN 15978) when assessing the impact of various redevelopment models. In other words, the report was recommending the holistic analysis of the life-cycle of the building including the social, environmental and economic impact of a development from inception through construction, use, demolition and recycling, rather than simply seeking a supposed short-term economic gain by selling the sites to developers. The cradle-to-cradle Life-Cycle analysis typically has 14 stages covering the full life-cycle of the building, including its operational emissions, but such an approach is not mandated in Australia. Only one state of Australia, New South Wales, requires analysis at the inception of a project of the embodied emissions in the first 3 stages of the Life-Cycle Analysis approach: raw material supply, transport, and manufacturing. Because of this limited approach the feasibility and total environmental, social and economic impact of projects is only partially analysed and accounted for.

The OFFICE report examined the benefits and costs of three redevelopment models; Demolition & Rebuild, Retrofit, and Retrofit & Rebuild against four criteria: Built outcome; Climate resilience; Health, wellbeing and community; and Economic impacts. The report cited three examples of European redevelopments that illustrated the three redevelopment strategies:

Demolition & Rebuild: Hygate Estate, London, England
Retrofit: *Cité du Grand Parc*, Bordeaux, France
Retrofit & Infill: Ellebo Garden Room, Copenhagen, Denmark

Of the three, the demolition and rebuild option provided the least satisfactory result against many of the criteria. Importantly the economics were disastrous for Southwark Council that had owned the housing estate.

Figure 2. Harrison & Abramovitz, Former Republic National Bank Building, Dallas, USA, 1954, central tower adapted to apartments 2005-2007 by Corgan Associates. In the foreground is Thanksgiving Square Chapel by Philip Johnson, 1964-1976. ©Scott Robertson, 2017.

Figure 3. Teo Gofers (Housing Commission of NSW), Sirius Building, Sydney, Australia, 1978-1979 with 2022-2024 assitions by BVN Architecture. ©Scott Robertson, 2024.

Southwark Council sold the site to the developer for £50 million. Southwark Council spent £44 million relocating and rehousing the 3000 tenants and £22 million on other development costs. The new development provided 82 social housing units in lieu of the original 350 residences and the remainder of the development was sold primarily to overseas investors.

5. UPGRADING THROUGH CONSERVATION. CITÉ DU LIGNON, GENEVA, SWITZERLAND

The upgrade of post-war housing estates need not involve demolition or the Lacaton & Vassal-type additions that transform the building into someone else's architectural creation. Other European examples can provide exemplars of good conservation practice that respect original fabric as well as provide a model of how to upgrade environmental performance and compliance with current regulations.

An important example is the *Cité du Lignon*, perhaps the world's longest and largest apartment complex containing 2,870 dwellings, that was designed by architects Georges Addor, Dominique Julliard, Louis Payot and Jacques Bolliger, and constructed between 1963 and 1971. The site was heritage listed in 2009. The heritage-listing of the aluminium and timber curtain walling and the introduction of new thermal building regulations were the catalyst for research into how to upgrade the complex. From 2008 to 2012 the research on

how to improve the building's thermal performance was undertaken by Franz Graf and Giulia Marino of the Laboratory of Techniques and Preservation of Modern Architecture (TSAM) in Lausanne. In 2011 Jaccaud Spicher Architectes Associés (JSAA) was appointed as architect for the refurbishment project that lasted 12 years. The works involved the fire and thermal upgrading of the exterior walls and the upgrade of services within apartments.

The rehabilitation works at the *Cité du Lignon*, are a paramount example of how the cultural significance of the building, including its aesthetic significance, has been maintained whilst the thermal comfort, the energy consumption, the services and safety of the building have been upgraded in compliance with current standards. This project is an exemplar of what can be achieved if the significance of a place is understood and respected as part of the upgrade process.

6. CONCLUSION

Projects such as the *Cité du Lignon* prove that retention of significance through conservation on one hand, and the upgrading of a building's thermal and overall environmental performance on the other, need not be mutually exclusive. What is required is a combination of humbleness of approach involving the sublimation of ego in order to permit the original design intent to remain or to be regained, as well as a regulatory environment that comprehensively values the social, environmental and economic impacts of the different models of building development and refurbishment. Only if such conditions are met can the ideals of the Eindhoven-Seoul Statement be met in the conservation and (re)use of buildings and sites of the Modern Movement so that those conservation and reuse works do no destroy or disfigure those significant examples of the Modern Movement. ■

BIOGRAPHY

Scott Robertson is an architect in private practice in Sydney. He lectured and tutored at the University of NSW and the University of Sydney for a period of 20 years and has delivered a number of public lectures, architecture tours and a national TV appearance on architectural styles and conservation. He is the author of a state-wide study of interwar housing as well as studies for the Heritage Council of NSW on sites in NSW used as part of the war effort in both World Wars and a recent survey of significant architecture of the last quarter of the twentieth century.

DECLINE OF DEPARTMENT STORES AND THE ISSUE OF 'THIRD PLACES' IN GERMAN INNER-CITIES: DECLINE, OBSOLESCENCE AND REUSE POTENTIALS

ANICA DRAGUTINOVIC
TH OWL, DETMOLD SCHOOL FOR DESIGN, DETMOLD, GERMANY

UTA POTTGIESSER
TU DELFT, FACULTY OF ARCHITECTURE AND THE BUILT ENVIRONMENT, DELFT, THE NETHERLANDS / TH OWL, DETMOLD SCHOOL FOR DESIGN, DETMOLD, GERMANY

ABSTRACT

The paper explores the rise and fall of the Karstadt department stores, which used to be the focal points of many German inner-cities throughout the twentieth century. The paper addresses the current issues of their obsolescence, decline and a recent increase in vacancies of the buildings. The desolation of those, once vibrant 'third places' – commercial entities, but also communal spaces, where people could meet and socialize – is asking for reuse scenarios, and thus requires an assessment of those buildings, understanding of the layers of history, analysis of their values, but also their potentials to adapt to changing circumstances and societal needs. While focusing on this particular typology of the inner-city department stores and the specific case of Karstadt buildings, the paper aims to address the issue of decline of various retail facilities, but also a general decline of 'third places' in cities. The term 'third places' was coined by a sociologist Ray Oldenburg in 1989, and denotes places beyond home (the primary place) and work (the secondary place) such as community centres, cafes, public libraries, theatres, public parks, etc. The study aims to better understand both causes and socio-spatial effects of their decline, correlating it with the digitalisation shift, changes in retail culture, but also blurred conventional separation between the first, the second and the third places (emergence of the so-called co-living, co-working and co-mingling spaces). It presents several case studies and research focusing on reuse potentials. The paper argues that the 'third places' have an important role in the well-being of local communities, in enhancing social cohesion, civic engagement and sense of belonging, and therefore need to remain focal in adaptive reuse proposals.

1. INTRODUCTION

The emergence of post-war ´modernity´ in Europe is commonly portrayed as "intimately entangled with state-driven actions", as noted by Gosseye and Avermaete.[1] Nevertheless, apart from the state, civil society and the private sector contributed to the introduction of the modern elements in the built environment. Amongst other products of modernity, the private sector particularly contributed to development of consumption spaces, including the shopping centre. However, as argued by Gosseye and Avermaete, "the role that corporate and commercial modernism played in reforming post-war Europe is still astonishingly understudied"[2]. In particular the typology of the shopping centre is under-represented. Therefore, this paper aims to contribute to the gap and shed light on this "other modernity", particularly focusing on the development of the inner-city Karstadt department stores in German cities.

2. COMMERCIAL COLLECTIVITY AND THE INNER-CITY DEPARTMENT STORES IN GERMANY

The conception of the department stores to function as the focal points of German inner-cities differed from the commercial complexes based on the American model of suburban shopping malls. The inner-city department stores emerged as a "tool for urban revitalization", "called upon for its (assumed) capability to renew the city and re-establish urban vitality" – as well as a modern consumer society.[3]

The emergence of the inner-city department stores in German cities followed the rise of global mass consumerism, which introduced more inclusive patterns of consumption, aligned with the "social market economy" or *Soziale Marktwirtschaft*. Their design was to embody it. The Karstadt department stores were designed and built as architecturally coherent facilities, predominately enclosed structures in the high-dense, central urban areas. As such, they offered a new urban experience to the ´consumer-citizens´, an experience of ´commercial collectivity´ in urban context.

One of the largest department stores built by this leading retail company of the post-war period in Germany – Karstadt AG – was built in 1964 in the heart of the city of Bielefeld, as the 54. department store of this retail chain in Germany. The four-story building, located in the main pedestrian street, was designed by the construction department of the Karstadt AG in cooperation with the local architect Karl Obbelode. The facade of the building was designed by the architect Hanns Dustmann. In April 1964, the department store was festively opened followed by a music band standing on the canopy above the main entrance, with around 80.000-90.000 visitors[4] (see **Fig. 1**).

The department store served for a multitude of needs and activities of the modern ´consumer-citizens´. It acted as a focal point for the "other" functions, fulfilling necessities and leisureliness beyond the "primary" (housing) and the "secondary" (work) places, as phrased by a sociologist Ray Oldenburg. Oldenburg[5] coined the term "third places" to denote places beyond home (the primary place) and work (the secondary place) such as community centres, cafes, public libraries, theatres, public parks, etc.

5. Ray Oldenburg, *The Great Good Place: Cafes, Coffee Shops, Community Centers, Beauty Parlors, General Stores, Bars, Hangouts, and How They Get You Through the Day*. New York: Paragon House, 1989.

There was a need for the "other" functions, or the "third" places, and in particular places of collectivity in the urban environment. This need was recognised and commercialised, thus incorporated in the setting of the shopping centres, or in this case department stores, offering an "alternative definition of the collective realm".[6]

Besides retail, the Karstadt department stores included entertainment and programs such as photo-laboratories, DIY sections, as well as exhibition spaces and spaces for socialisation, as it was the case of the Karstadt department store in Bielefeld. One of the exhibitions was a four-week exhibition of the Art and Culture of the Continent, opened in August 1970 with 2.500 objects from 14 countries presented and offered for sale – including dance drums and masks from Nigeria and instruments from Bali.[7] The cultural activities acted in the service of commerce and contributed to the sales annual result (almost 160 million DM annually in the mid 1970s, as reported by the archive of the city of Bielefed).[8]

3. DECLINE OF THE KARSTADT DEPARTMENT STORES

After the peak in the 1970s, around 10 years later, the department stores faced the first crisis. In order to maintain the attractiveness, in the following years the company invested in renovations of the department stores. However, despite those efforts, by the end of the 1980s the department stores faced de-growth in terms of the annual results in sale, as well as in the number of employees (e.g., the department store in Bielefeld had a decrease from 1.200 to 570 employees in 1989, as reported by Vohwinkel).[9] Further investments in modernisation of the department stores followed in the beginning of 2000s, but the trend of decline remained. Eventually, the Karstadt company faced insolvency, and the department stores changes in ownership, further decline in sale and the number of employees (e.g., in 2014 the department store in Bielefeld had around 170 employees, as reported by Vohwinkel).[10]

Currently, the Karstadt department stores – in total 90 stores (or, after the merge with Galeria, in total 129 stores) throughout Germany – are facing vacancies and gradual desolation. In some cases, e.g., in the case of the Karstadt department store in Hamburg, the city bought the building, and a temporary purpose is planned until the competition for the new concept is conducted. Some of the department stores, e.g., the department stores in Dresden, Chemnitz, Erfurt and Magdeburg are expected to remain and be modernised in the upcoming period.

Some of the buildings, e.g., the building in Magdeburg designed by Karl-Ernst and Anne-Monika Zorn in 1970, have very recognisable appearance and facade design. (see **Fig. 2**) Also, the size of the buildings, which is usually much bigger compared to the surrounding, contributes to them remaining remarkable within the urban landscape they were built in.

The altered patterns of consumption, changes in the retail culture and the digitalisation shift have an additional impact on the plans to dissolve the department stores and re-purpose the buildings.

8. Vohwinkel, "22. April 1964: Eröffnung der Karstadt-Filiale an der Bahnhofstraße", 2024.

9. Vohwinkel, "22. April 1964: Eröffnung der Karstadt-Filiale an der Bahnhofstraße", 2024.

10. Vohwinkel, "22. April 1964: Eröffnung der Karstadt-Filiale an der Bahnhofstraße", 2024.

Due to the scarcity of the 'third places' and community spaces in German inner-cities, in particular the non-commercial ones, the conversion or adaptive reuse plans for the vacant department stores need to consider involvement of different spaces for leisureliness and collectivity in order to improve the vitality of the inner-cities, enhance social cohesion and sense of belonging. In that way, the buildings would preserve their primary role as places of collectivity in the urban environment, yet de-commercialised and suited to the contemporary needs of the citizens and local communities.

An additional change that has an impact on the use and reuse of those spaces is that the conventional separation between the first, the second and the third places is becoming more blurred, leading to the emergence of the so-called co-living, co-working and co-mingling spaces. This too needs to be considered when creating future reuse scenarios.

4. REUSE POTENTIALS FOR THE KARSTADT DEPARTMENT STORES

Possible reuse of the Karstadt department stores was set as a task and explored within a research-oriented Master module "C5 Conference and Communication", at TH OWL in Detmold (Germany), led by the authors. In total 16 interdisciplinary student groups conducted a study on reuse potentials while focusing on different case studies of Karstadt department stores. (see **Fig. 3**)

The groups were focusing on different aspects of past, present and future of the Karstadt department stores, in particular exploring the questions of urban identity, the role of digitalisation and altered shopping behaviour; as well as developing an analytical and assessment framework applicable to the department stores, and assessment of facade components through a digital facade autopsy.

The facade autopsy method is involving comprehensive documentation, disassembly, material identification and testing, which provides a deep understanding of the existing facade components, perceived as a "material bank". The method is crucial in identifying potential for material reuse and recycling in case of buildings not recognised as architecturally significant, and in assessing the environmental impact of facade materials, providing architects with valuable insights for informed decision-making in the reuse process.

Furthermore, some of the groups were exploring what are decisive measures for creating a sense of belonging in reuse scenarios and how to transform the buildings into vibrant community hubs.

The students particularly recognised the capacity of the buildings to re-emerge as catalysts of urban revitalization, community development and overall well-being of the citizens. Transforming the vacant department stores into community centres and cultural hubs can provide opportunities for social interaction, facilitate community engagement and foster community cohesion.

One of the groups recognised a critical factor for reuse of the department stores, which is their closed facades, and explored possibilities of increasing the amount of natural light in the buildings. Depending on the new program

for the building, they proposed daylight optimisation to suit the new function, e.g., creating a light shaft and re-designing the facade.

Additionally, in order to improve visual connectivity with the city and mitigate the closed-off atmosphere often associated with the large department stores, it is necessary to open up the building, re-design its facade as a more porose structure and re-configure pedestrian paths to optimize the flow and accessibility, as concluded by one of the groups.

5. CONCLUSION

The study explored the inner-city department stores as one of the typologies of the "commercial" modernism, which played as well an important role in reforming urbanity in the post-war Europe. These commercial facilities strongly contributed to the creation of the modern consumer society, offering a new urban experience to the 'consumer-citizens', an experience of 'commercial collectivity' in urban context.

The study of the past, present and future of the Karstadt department stores shows how those once vibrant 'third places' – commercial entities,

but also communal spaces – became obsolete and are facing increase in vacancies. Although some of the buildings have very recognisable appearance and remain remarkable within the urban landscape they were built in, they urge adaptation in order to suit the changing circumstances and societal needs.

The paper presents findings from the Master module, which was assessing and exploring reuse potential for the Karstadt department stores in German inner-cities. The findings highlight the capacity of the buildings to re-emerge as catalysts of urban revitalization, community development and overall well-being of the citizens. This needs to remain focal in adaptive reuse proposals. Possible multifunctional cultural hubs and comparable programs, which were the most commonly addressed in the student works, could facilitate diverse activities, including social gatherings, workshops, cultural events, and tailored services, addressing the nuanced needs of the citizens.

Nevertheless, as noted by one of the student groups, development of the transformation process for the department stores necessitates meticulous city-specific analysis, the formulation of a comprehensive space catalogue, and the strategic planning of interventions for optimal effectiveness. ■

BIOGRAPHY

Anica Dragutinovic, DR. (PHD), M.ARCH., is an architect, researcher and lecturer, holding a PhD in architecture from TU Delft | ABE (the Netherlands). Her PhD research was focusing on the modern and recent heritage, and in particular mass housing issues. Anica is currently engaged as a Post-doc Researcher on a DFG project and a Docent at TH OWL (Germany). She is involved in RMB Reuse of Modernist Buildings project and was a member of HvdV research group at UAntwerpen (Belgium). She was engaged as a researcher and project manager in SHA and FOMA projects within DOCOMOMO Germany.

Uta Pottgiesser, DR.-ING. (PHD), licenced architect (1993), studied Architecture at TU Berlin (1984-91) and finished her dissertation at TU Dresden (2002) in Germany, with the title: Multi-layered Glass Constructions. Energy and Construction. She is Chair of Heritage & Technology at TU Delft in the Netherlands (since 2018) and Professor of Building Construction and Materials at Detmold School of Architecture and Interior Architecture, Germany (since 2004). As a practicing architect and academic she is concerned with the protection, reuse and improvement of the built heritage and environment; and she is a board member of DOCOMOMO Germany since 2016 and the chair of the DOCOMOMO International since 2022.

ADAPTIVE REUSE OF MODERN HERITAGE: ATTITUDES IN RELATION WITH THE MATERIALITY OF DÉJÀ LA. CASE STUDY OF THE CITROËN GARAGE (1934) BECOMING KANAL (2018)

CHIARA FUCELLI
UNIVERSITE LIBRE DE BRUXELLES

ABSTRACT

In adaptive reuse, we can assume that the existing site is an open work that questions and can be questioned. From this perspective, the strategy chosen by an architect/designer depends on the context. The existing elements are there as memories of a past to be reused, rewritten[1], reactivated.

This article investigates the relationship between the materiality of the *déjà la* (and the need to transmit it) and the practices of architects, through the analysis of design proposals from the *Kanal* international competition in Brussels. This analysis investigates the project strategies of architectural proposals, focusing on their conceptual and representational aspects. It compares architectural production with texts written by and about architects. The aim is to understand how teams of architects preserve and enhance the memory of the "Kanal lieu (Garage Citroën Yser)", while responding to the requirements of a museum of modern art and a public space.

1. INTRODUCTION

The Icomos charters and documents have influenced the practice of intervention in existing buildings since the *Athens Charter* (1931). The *Venice Charter* (1964) refers to aesthetic and historical values, linked to a materiality based on the image to be transmitted. *The Nara document on authenticity* (1994) states in point 13 that, when faced with a site, we must verify and analyze a series of sources which, in the end, will give direction to the architectural intervention. Therefore, what is the best way to intervene, bearing in mind that in some projects new elements have to be introduced by necessity or simply to revitalize sites?

Architects also have a personal background that they bring with them and that influences their choices. This background comes from their culture, from their practice, and from their memories.

In the publication, *A Feeling of History* (2018), Peter Zumthor describes to project on a specific site in terms of its emotional reconstruction: "it stimulates empathy and curiosity about the place". Zumthor underlines the importance of the chosen materiality and sees architecture as a medium for revealing history. According to architecture critic Pierre Chabard, through architecture Peter Zumthor does not transmit history (as the past of the present), but memory (as the presence of the past). "Emotional reconstruction does not provide a sense of history, but orchestrates the dramatized spectacle of a theatre of memory" [2].

The competition for the site of *Kanal* was launched by the Fondation KANAL[3] in 2017 with the aim of transforming the modernist *Citroën* garage (Alexis Dumont, 1934) into a new kind of cultural site hosting the two institutions partners (CIVA[4] and Centre Pompidou[5]), intended for neighbors, inhabitants of Brussels and tourists alike. It is planned to design a museum of modern and contemporary art, a museum of architecture, a library with architectural archives, as well as public spaces dedicated to various artistic and recreational activities.

The competition was won by the architects' association noAarchitecten (BE), EM2N(CH) and Sergison Bates architects (UK); the other six finalist teams were: Advvt(BE), 6a(UK) and AgwA(BE); OMA/AMO(NL) and Wessel de Jonge architecten(NL); JDS(BE) and Diller Scofidio Renfro(USA); Office KGDVS(BE) and Christ and Gantenbein(DE); Lhoas & Lhoas(BE) and Ortner & Ortner(DE); 51N4E(BE), Caruso St-John(UK), l'AUC(FR) and Thomas Demand(DE). In this article, for reasons of format, we analyse and compare the proposals of 3 teams: OMA/AMO and Wessel de Jonge architecten; OFFICE and Christ & Gantenbein; 51N4E, Caruso St-John, l'AUC and Thomas Demand.

The garage is not considered as a monument, but its architecture is significant for the community and the intention was therefore to preserve it.

How to transform what was formerly a symbol of modernity, a garage where cars were not only designed and manufactured, but also showcased, into a cultural container?

By identifying topics that guided the different strategies (heritage, new ecology, phenomenology, effacement, etc.), adaptive reuse attitudes in relation with the materiality of the building will be highlighted.

3. Created by the Brussels-Capital Region, the primary mission of the KANAL Foundation is to successfully complete the conversion of the Citroën garage.

4. CIVA is the Brussels-Capital Region's center for information, documentation and exhibitions on the city, architecture, landscape and urban planning, CIVA is a museum, archive center, library, meeting place and forum for mediation and discussion on architecture, landscape, urban planning and ecosystems.

5. The *Centre national d'art et de culture Georges-Pompidou* (CNAC) - better known as the 'Centre Pompidou', its main location is in Paris.

2. THE ORIGINAL GARAGE

The Citroën garage, built in 1934 by Alexis Dumont (1877-1962) covers an area of 16500 m2 and consists of two units, the showroom and the workshops. The workshop, which occupies the majority of the site, was the production area and consists of a repetitive metal structure of prefabricated latticework. The structure is covered by a roof made up of glazed elements, and enveloped by a curtain wall, also glazed, that runs around the perimeter of the plot.

The showroom on the boulevard, Citroën's showcase, was intended to be an attractive space representing the brand's spirit of innovation. This is reflected in the 21-metre-high, curved, all-glass volume.

The Citroën garage is a typical example of the *licht-architektur*[6] era. The technical nature of the structure and the massive use of glazed surfaces give a feeling of lightness to the whole, creating a continuous, flexible space bathed in light.

In its early days, the garage was a free space in its entirety, ready to be used and capable of accommodating several functions around car production and sales. One of André Citroën's concepts was to create hybrid buildings, cities within cities, combining not only showrooms, administrative areas, services and workshops, but also other facilities for customers, such as petrol stations, newspaper stands, hairdressing salons, restaurants and even cinemas and temporary exhibition areas under the same roof.

In 2017, the garage is presenting two mains modifications. In the post-war period, a concrete intermediate floor was added to the workshop section. Structurally, the original building "had the load-bearing capacity and height to accommodate a concrete floor, without the need to modify or reinforce the original structure". In the 1950s, on the showroom side, five concrete floor levels were added, this time with a concrete structure completely detached from the existing structure.

3. CASE STUDIES

3.1. OMA/AMO AND WESSEL DE JONGE ARCHITECTEN: ELIMINATION AND HYBRIDISATION - THE EFFACEMENT

During a lecture at Columbia University in 2009, Rem Koolhaas says that the act of preservation has become a refuge for architects to escape the derisive label of "starchitect" that is attached to them. Rem Koolhaas talks of preservation as a revolutionary act against the economic system, against the ecological system that encourages the destruction of historic buildings, by financing the purchase of new materials to rebuild in a sustainable way, rather than guaranteeing the preservation of existing resources.

In line with this 2009 statement, OMA/AMO and Wessel de Jonge architecten show a certain self-effacement in its project proposal for Kanal. Three main eliminations are made in order to "free up what will become the key spaces of the project"[7]. The first elimination removes all non-structural elements from the central axis that connects the site east-west. The second elimination empties the north-south corridor, allowing a direct connection

6. Workshop & Showroom group, IPW3, RLICC - KU Leuven Academic year 2013-2014, *Garage Citroën Brussels* (Leuven: Raymond Lemaire International Centre for Conservation, 2015), 13.

7. Oma, *Kanal le garage du XXIème siècle*, Competition dossier for Kanal (Brussels : Oma, 2017), 5.

between the showroom and the museum. The third elimination consists of removing all the floors in the showroom, except the last one.

What remains of these more or less extensive eliminations will, by default, define the forms of the institutions: theatre, showroom, museum, offices, etc. In these places found, or rather searched for and defined in the garage environment, architects insert functional technical elements and lightweight structures to keep these spaces modular. Among the elements that catch our eye, because they are foreign to the original garage, are the orange-red portal frames. These are overhead travelling cranes on wheels, used to hang stage backdrops adapted to the various events at the cultural center. By their very presence, these frames become architectural elements that help to characterize OMA's intervention. In the Zollverein Museum in Essen and the *Fondaco dei Tedeschi* in Venice, in addition to the attitude of formal effacement, it is also possible to find the introduction of color by OMA, red or orange, to underline the new technical elements, in both cases staircases. Another feature borrowed from a previous project is the steps in the museum area and the showroom. The same proportions can be found as in the Prada boutique in New York. The museum steps use the same spatial configuration in conjunction with an elevated walkway.

With the principle of elimination, OMA/AMO and Wessel de Jonge architecten manage to recover certain meanings of the original garage (showroom volume, clear axes). Compositional erasure makes it possible to preserve the phenomenological characteristics of garage by default. The punctual installation of devices taken from the OMA vocabulary (bridges, steps) constitutes the last stage in the rewriting of the site through its own vocabulary, and is inserted in a way that is detached from the existing structures, leaving a certain degree of reversibility.

3.2. OFFICE AND CHRIST & GANTENBEIN - RETURNING TO THE ORIGINAL STATE, A PICTURESQUE AND RADICAL POSTURE

The strategy adopted by the team of OFFICE Kersten Geers David Van Severen and Christ & Gantenbein for the renovation of the Citroën garage is to free the space of any additions in order to restore the garage to its original state, and to concentrate all the functions in two pure, identifiable volumes.

The qualities looked for, such as "height, magnitude and light"[8], are those intrinsic to the building state of 1935. Additions from successive eras are considered impure and uninteresting. It is therefore necessary to free the existing building of all elements considered to be obstructions, such as floors and partitions added after the date of construction, in order to restore the original structure.

Once the purity of the pristine state has been restored, the showroom serve as a showcase for artistic installations. The spaces cleared from the workshop are similar to *halles* and will be used as protected outdoor spaces, with a pleasant but uncontrolled climate.

Two main volumes have been inserted to accommodate all the functions that require air and light control: a parallelepiped and a cylinder. The

8. Office and Christ & Gantenbein, *Quartier Kanal*, Competition dossier for Kanal (Office and Christ & Gantenbein, 2017), 6.

parallelepiped, based on a warehouse typology that develops over five floors, hosts the museum. In return for this sublimation of the existing structure, a large part of it will have to be demolished in the workshop part to insert the two volumes.

The architects evoke a parallel with the Cordoba mosque as a generative approach. While the source of inspiration seems appropriate from a philosophical point of view, the proportions between the existing regular structure and the new volumes are not quite the same as those of the Mesquita in Cordoba. The sculptural nature of the new volumes is reinforced by their size and language: solid walls punctuated by voids inserted at specific positions, like in the Swiss National Museum extension by Christ & Gantenbein in Zurich.

In OFFICE and Christ & Gantenbein project, the relationship with the past is contemplative, with a nostalgic note suggested by the planting associated with the existing building, as in a picturesque image. However, by its very nature, the garage, a symbol of technical progress and optimism, is intended to be used for activities rather than to be contemplated. From our point of view, this example shows that even if the phenomenological characteristics of a place are retained, its meaning can still change. The way a place is perceived can be radically different depending on how it is exploited.

3.3. 51N4E AND CARUSO ST-JOHN, L'AUC AND THOMAS DEMAND; EXISTING AS A RESOURCE - THE QUEST OF MEMORABLE PLACES

In their proposal for the Kanal museum, architects 51N4E, Caruso St-John l'AUC and Thomas Demand consider the museum as a public infrastructure.

Their project is described in three strategies[9]. The first, linked to the existing building, consists of maintaining the building envelope as a kind of 'mantle' covering the cultural entities and events. This envelope is treated in an open and casual way, with modifications possible according to need. For example, all the glazing on the façade is replaced and new openings are created to break up the monotony of the original frame design. The roof can be modified, sometimes removed, sometimes preserved as it is, depending on what it shelters. The second strategy is to add identifiable architectural entities: the long gallery, the building dedicated to architecture, the showroom, the productive courtyard, the interval and the reservoir. Each of these entities has a different relationship with the existing building, creating a multitude of relationships with the existing structure. The third strategy is a temporal one, enabling synergies between cultural players. The project therefore remains open and adaptable, and the systems put in place should not be considered fixed.

Adam Caruso and Peter St John's practice is guided, among other things, by the search for new forms which, by analogy, provoke collective emotional responses. Here they propose six different spaces, memorable places each with its own characteristics, so that they are directly recognizable, allowing the cultural entities that settle in them to be identified. From the point of view of the design of these spaces, the existing structure becomes a background

where these different objects, which we can compare to follies, take place.

The implementation of various devices in existing buildings will bring with it constraints that will be dealt with on a case-by-case approach. In this series of approaches, the existing remains in the background, when it is not totally hidden or transformed.

In the *The Triple Folly* in Ebeltoft, Denmark 2017-2022, a project by Caruso-Saint-John in collaboration with the artist Thomas Demand, formal similarities can be found with the entities designed for Kanal.

In accordance with the intentions expressed in the competition dossier, the architects consider the existing as a resource; their primary intention is therefore not to sublimate the existing, but to safeguard it in order to create devices that create different relationships with it. The existing, as a resource, is at the service of the project and even if the materiality of the *déjà là* is safeguarded, reasonable doubts may arise as to the preservation of the intrinsic spatial and formal characteristics of the garage.

4. CONCLUSION

All projects fulfilled the specifications, defined with the intention to preserve the existent. However, this analysis allows us to identify different approaches/attitudes to the materiality found on the place. While in the project by 51N4E, Caruso St-John, l'AUC and Thomas Demand the existing matter is a support behind the new features, in the proposal by OFFICE and Christ & Gantenbein the same matter returns to the forefront in opposition to the new devices. In the OMA/AMO and Wessel de Jonge architecten proposal, the intervention strategy goes beyond material as permanence; the

locus is considered in the wholeness of its multitude of phenomena; existing matter is neither behind nor besides, but "in" new devices.

In OMA/AMO and Wessel de Jonge architecten proposition, the elements that characterize the place participate (and are) in the new devices. The new devices are designed to take advantage of the specific characteristics of the existing space. The existing is in the new and vice versa. The old and the new are thus intertwined.

In OFFICE and Christ & Gantenbein proposition, the elements that characterize the place stand side by side with new devices. The new devices refigure the existing space. The old and the new coexist in a new way, while maintaining a dialogue fundamentally based on contrast, and thus remaining identifiable.

In 51N4E, Caruso St-John, l'AUC and Thomas Demand proposition, the elements that characterize the place stay in the background of new devices. What already exists becomes a support for the introduction of new features. Existing elements remain in the background, visible or hidden by the new devices.

It is also noteworthy that the more the characteristics of the site are consciously taken into account in the design process, the less the architects' distinctive design elements take space. ■

THE OCEAN TERMINAL COMPLEX, DURBAN: THE SEARCH FOR MEANING IN AN IRREVOCABLY CHANGED CONTEXT

MIKE SCURR
DOCOMOMO SOUTH AFRICA
RENNIE SCURR ADENDORFF ARCHITECTS, CAPE TOWN

ABSTRACT

The buildings and related infrastructure comprising the Ocean Terminal complex at Durban harbour, South Africa, were completed in 1962. The design of the new complex had been awarded to Zakrzewski & Partners Consulting Engineers in 1958, with Architect Janusz Warunkiewicz appointed as architect in 1959.

Despite being one of the key modernist works in South Africa, the entire complex is now earmarked for total demolition to accommodate open storage of container units and motor cars, key elements of modern maritime trade.

The objective of this study is to consider the historic and contemporary meaning and significance of the place, its relevance in a society that has undergone fundamental change and its role in an economic context markedly different from its original function.

The paper is derived from a research project the author undertook to establish the heritage significance of the place and to explore prospects for conservation. Detailed on-site work as well as archival research was undertaken.

The outcomes of the study demonstrated that the degree of architectural, technical and artistic innovation and excellence suggest that its total removal should not be considered, despite loss of function and context.

Ultimately however, the political and economic arguments held sway and the likely outcome is total demolition, leading to a loss of an iconic set of structures in the Durban harbour. While the heritage process and study ensured that the significance of the complex was placed centrally in the debate, another economic and political model would be required to realise a different outcome.

1. INTRODUCTION

1.1. AIM OF THE STUDY

The Ocean Terminal complex situated on the T-Jetty at Durban Harbour, South Africa, is an approximately 800m long sequence of built spaces including road interchanges, ramps, cargo handling facilities, port operations, passenger embarkation and disembarkation amenities, public piazzas and a promontory, with a vast passenger terminal at its centre, sited adjacent to cruise liner berths. The building complex represents an inventive, coherent and masterful interplay between civil engineering, architecture and art. However, despite the very high (Grade II)[1] heritage grading and recognition as one of the key modernist works in South Africa, the entire complex is now earmarked for total demolition to make way for open storage of container units and cars, key elements of modern maritime trade.

The objective of this study is to consider the historic and contemporary meaning and significance of the place, its relevance in a society that has undergone fundamental change and its role in an economic context markedly different from its original function.

The paper is derived from a 2022 research project[2] the author undertook to establish the heritage significance of the place and to inform and explore prospects for conservation. Detailed on-site work as well as archival research was undertaken.

1.2. ORIGINS OF THE OCEAN TERMINAL COMPLEX

The design of the new Ocean Terminal Complex was awarded to Michal S Zakrzewski & Partners Consulting Engineers in 1958, while Polish architect Janusz Warunkiewicz[3], recruited by Zakrzewski, was appointed as project architect in 1959. The overall structure was completed in 1962[4]. The multi-disciplinary team included architect Hans Hallen, engineer Milek Masojada, and artist John Hooper. Hooper's quirky and colourful sculptures throughout the complex provide a counterpoint to the modernist detailing and materiality.

The work was initiated to facilitate the growing export industry and also steam ship passenger travel between South Africa and UK, driven by the Union-Castle Mail Steamship Company which docked weekly at Durban and departed with passengers and 4000 tons of fruit. The proposed terminal had to provide storage for cargo in transit, as well as fruit (including pre-cooling facilities to slow the ripening process during the long journey North), and facilities for embarking and disembarking passengers, together with their baggage and cars. This multi-functional role was fulfilled by designing an ingenious building complex that performed its various functions from different levels of a single structure aligned along the wharf edge, with a stratified sectional profile very like the cruise liners it serviced.

1.3. DESCRIPTION OF THE BUILDINGS

The Ocean Terminal Complex encompasses a site-wide intervention stretching the entire length of the c1945 constructed T-Jetty with space being organised both horizontally and vertically. The layout stretches from the raised circular

1. The National Heritage Resources Act (NHRA) of South Africa (1999) has a three-tier system of grading with Grade I being National Heritage Sites, Grade II Provincial Heritage Sites, and Grade III, locally managed heritage resources.

2. Rennie Scurr Adendorff, *Durban Harbour Heritage Scoping Report as a Precursor to S.34 and/or S.38 Submissions to AMAFA*. Unpublished Report, 2022.

3. Docomomo South Africa (2023). Warunkiewicz emigrated to Canada shortly after this project, where his notable projects include the design of metro stations Place-d'Armes and Henri Bourassa, Montreal and 'La Pyramide' apartments on Nuns' Island, Montreal). He died in Toronto in 2015 a few weeks short of his 105th birthday.

4. Rennie Scurr, *Durban Harbour Heritage Scoping Report as a Precursor to S.34 and/or S.38 Submissions to AMAFA,* 2022.

roadway interchange in the north, allowing goods trains to pass unhindered underneath, with a series of raised goods and parking decks atop which sit the two iconic centrepieces of the complex, running along to the end of the pier terminating in a circular car ramp and a sculptural stair and viewing pavilion.

Space was organised horizontally in plan with duplicated and segregated spaces for 'Europeans' and 'Non-Europeans'[5], thereby spatially entrenching the Apartheid ideology of the era. Vertically, goods and passenger handling happened simultaneously in one building. The terminal hall was raised to be level with passenger decks and so passengers traversed from the parking area, through the grand volume of the Ocean Terminal itself to check-in and then across to telescopic gangways connected to the ocean liners. Spatially, the inventive and unique design has more in common with modernist rail terminals such as Termini in Rome and contemporary railway and airport designs than it does with other wharf-side structures of the 1950s and 1960s, such as its 1950 counterpart in Southampton, England.[6]

While the roadways, ramps and the first two building levels are largely functional, they nonetheless integrate inventive engineering as well as thematic architectural detailing that ties into the remainder of the complex. However, it is in the two centre-piece buildings where the architectural and engineering virtuosity is most clearly seen. These designs have links with international Modernism, notably Brazilian Modernism and clearly reference the work of both Le Corbusier and Oscar Niemeyer. The Durmarine administration/ Port-Captain's tower building and the Ocean Terminal itself, represent a high point of modernism in Durban and are richly detailed with an array of architectural forms and devices.

In the case of the Durmarine tower, these elements include V-shaped columns and a raised and recessed entry level, facade-wide metal sun screening on the North facade and curtain glazing with coloured spandrel panels on the South facade. The roof level has wrap-around glazing for the Port Captain's control area.

The Ocean Terminal building is richly imbued with mosaic and sculptural art offset against the clean concrete, glass and terrazzo interior. The main public space is conceived as a vast transport hall with precast tapered concrete columns and a sweeping, folded V-shaped concrete roof, with expansive glazing looking directly onto the docked cruise liners. The exterior is somewhat less refined than its interior, but also relies on alternating facade treatments; full glazing facing east onto the ocean liners and a facade comprised of metal sun screening on the West, carpark facade. Punctuating the linear entry facade is a marine-inspired sculpture by John Hooper[7].

A vital component contributing to the design and built excellence lies in the inventive and seamless integration of engineering, architecture and art, all in a building complex driven by an exacting functional programme.

1.4. SOCIAL AND ECONOMIC CONTEXT

The Ocean Terminal complex was informed by key events that impacted South Africa's economic and political history. The global boom that followed the end

5. Terminology as per racial classification of the South African population in the apartheid era.

7. The artworks integrated in the complex include mosaics and sculptures by Armando Baldinelli from Italy, John Hooper from England and James O Hall from New Zealand. https://www.worldofinteriors.com/story/ocean-terminal-building-durban-south-africa-modernist-architecture Last Accessed 2024.06.10.

of World War II and, locally, the impact of the 1948 ascension to power of the National Party government in South Africa created the need for the large, modern terminal but also informed its programme and purpose.

Durban was well positioned to respond to the boom in globalised trade, and by the early 1970s it was the country's biggest seaport and the 11th largest commercial port worldwide, handling more cargo than all other South African ports combined.[8]

Alongside this growth, apartheid legislation entrenched in law the policies of segregation and exclusion that had been in place from the mid-1800s. A suite of legislation determined where black South Africans may live, their movement, and restricted them to unskilled labour. In June 1958 Durban was zoned as a White Group Area and the city reserved for white people, with all people of colour relocated to racially designated areas to the north and south.

In 1960, because of these policies, South Africa was pushed to leave the British Commonwealth and in 1961 became a Republic. However, while policies promoting separate development and white supremacy were criticised outside of South Africa, neither trade in cargo nor tourism was immediately impacted until the sanctions era of the 1970s and 80s. Durban Port embarked on a decade of intense expansion and development. The Union-Castle line with its weekly Royal Mail service continued to promote South Africa as an exotic, fun-in-the-sun destination.

The Ocean Terminal Building's design and programme, however virtuosic from a technical and design point of view, remains essentially a product of the politics and economics of this period.

2. FUNCTIONAL AND SPATIAL CHANGES OVER TIME

2.1. END OF AN ERA

The demise of the Ocean Terminal was hastened by the concurrent impacts of commercial air travel, increasing containerisation as well as international sanctions imposed on the South African Apartheid state in the mid to late 1970s onwards. By then the hey-day of the mail-ship was over, and passenger demand for sea travel declined with the introduction of the Boeing 747 in 1971 as well as other larger commercial aircraft which made air travel both more accessible and more affordable. The buildings fell into increasing redundancy following the termination of the last Union Castle mail ships between the UK and South Africa in 1977, only 15 years after the construction of the Ocean Terminal complex. General administration, cargo and logistics functions continued and, in order to find a use for the grand space, the terminal hall was repurposed as offices in the early 1990's. Interestingly, the resurgence of cruise ships in more recent years resulted firstly in one of the older warehouses on T-Jetty being converted to serve passengers and, more recently, in the construction of a brand new cruise terminal[9] nearby in another part of the harbour and which opened in 2023.

2.2. A SECOND LIFE

In the early 1990s, as part of a business rationalisation process, the Ocean Terminal building was converted to provide over 5000 square metres of

8. As noted in the Standard Encyclopedia of South Africa (1972).

office space for a staff of 300 people.[10] Two mezzanine levels provided additional floor space either side of the row of central columns; these floors were set back from the outer walls to create double volume edge spaces that allowed natural light to penetrate in, and to provide extensive views over Durban Bay out towards the Bluff.

The conversion was done with some care and consideration for the existing building and its materiality: the terrazzo and mosaics were cleaned and conserved, hardwood from the customs counters was recycled as stair treads, and overall, the new insertion reads as secondary in character set apart from the original 1962 composition. However, the extent and programme of the insertion required new steel beams to be fixed to the central columns to support a new concrete mezzanine slab laid across the previously open area. Furthermore, the thin shell-like roof was obscured with an insulated ceiling slung underneath, while the space was fully air-conditioned and serviced. The overall clutter and heaviness of the 1990s detailing foregrounds the new "layer" and overwhelms the original.

While this development allowed the building to be used for another three decades (roughly twice the period of its first incarnation), and even though the physical intervention can be regarded as 'reversible' and 'lightweight', the true impact on heritage is clear. The programme and reuse of the space failed to respect the form, function and spatial quality of the original composition. The original design's inspiring interior volume and functional interconnectedness has been fully obscured and lost, existing only in memory and in archival images, despite the building still standing.

The over-riding heritage impact of this adaptive reuse has been to neutralise the building's spatial power and render it simply as real estate. In this way, any hope of saving it now becomes even more difficult.

3. CONTESTATION OF VALUES

3.1. CONTEMPORARY MEANING AND SIGNIFICANCE

The Ocean Terminal complex lies at the intersection of contested views on significance. Highly valued by the architectural community primarily, this author graded the key buildings and elements as Grade II heritage sites.

The Statement of Significance for both the Durmarine Building and the Ocean Terminal noted inter alia that "the building is one of the modern movement masterpieces in South Africa".[11]

The significance of the complex overall derives from its masterful spatial organisation (both horizontally and vertically), clear concept, highly skilled engineering and technical solutions and modernist detailing as well as the integration of mosaic and sculptural artworks throughout.

Ordinarily, such deemed significance could be expected to afford a level of protection and curb the development pressures. However, countering this is the fact that the complex lies beyond the port security cordon and is no longer publicly accessible. Apartheid legislation ensured that, by and large, only black South Africans who laboured in the complex experienced it, and latterly its removal from the public realm and conversion to mundane office

9. The Nelson Mandela Cruise Terminal, https://www.kcterminal.co.za Last Accessed 2024.06.10.

10. Laurie Wale "Ocean Terminal Durban". *Architect and Builder*, (July 1993): 6-10.

11. This proposed Grading was also endorsed by the Kwa-Zulu Natal Provincial Heritage Resources Agency, AMAFA, who also granted the Permit for the Demolition; Rennie Scurr, *Durban Harbour Heritage Scoping Report as a Precursor to S.34 and/or S.38 Submissions to AMAFA*, 2022.

space further consigned it to irrelevance to the broader public. Coupled with loss of function, the desire to demolish it is perhaps not hard to understand.

3.2. HERITAGE INFORMED SCENARIOS AND RECOMMENDATIONS

The outcomes of the author's study demonstrated that the degree of architectural, technical and artistic innovation and excellence suggest its total removal should not be considered, despite loss of function and context. Despite this, and understanding the political and economic will to achieve *tabula rasa*, a series of scenarios were proposed which would retain the two core buildings but lose the road and parking infrastructure portions in the hope that a future use could still be found. As one example, the return of the terminal to its open, bare shell state could potentially transform the space into a conference venue, or vehicle facility allied to the export trade. One such example offered is Saarinen's TWA Terminal at JF Kennedy airport in New York. There, the iconic nature and architectural innovation and excellence allowed the terminal to survive rampant airport development and emerge recently as a destination hotel, restored to showcase its 1960s design. This approach applied in Durban would require there to be a degree of economic viability and some consensus as to significance and value even to be considered.

Such a compromise in retaining only the core however neither satisfies architectural purists who see value in the whole composition, nor the Port Authority for whom the only viable option is in expanding the open container terminal loading areas and entrenching the no-public access secure zone.

4. CONCLUSION

While the heritage process and study ensured that the significance of the complex was placed centrally in the debate, another economic and political model would be required to realise a different outcome.

The result of the planned demolition will be a total erasure of the memory of the site as well as the loss of the highly significant and rare 1960's transport complex, and along with it, unique elements of South African architectural, engineering and artistic heritage. Countering this are arguments related to job-creation in a developing country, redundancy in the design and programme and the need for Durban port to meet the demands of worldwide trade in the 21st century.

Recent attempts to stave off demolition have been made in response to demolition Permits being granted. Ultimately however, the political, developmental and economic arguments held sway and the most likely outcome is total demolition, leading to a loss of an iconic set of structures in Durban harbour.

The role of Docomomo to document the building prior to its loss is recorded, but ideally this needs to extend to input into the planned Museum reflecting aspects of the building in a meaningful manner, and potentially even to identify elements for retrieval and reuse in the envisaged display.

In the South African socio-political context, the need to reframe the history of the Ocean Terminal Complex is also paramount. Instead of focussing only

on the architectural narrative of the design, the history also needs to address the role of black South Africans who laboured in the harbour and who built the complex, as well as the spatial apartheid which existed throughout the lifespan of the Ocean Terminal, thereby providing some opportunity for redress. Demolition and economic development alone can never achieve this. ■

BIOGRAPHY

Mike Scurr is an Architect, heritage consultant and Director of Rennie Scurr Adendorff in Cape Town, South Africa. He graduated from UCT with a degree in Architecture and later an MPhil in Conservation. Mike has over thirty-five years' experience working on heritage and conservation projects. Current commissions include the post-fire rebuilding of the Parliamentary complex in Cape Town, conservation work in the historic old town of AlUla, Saudi Arabia and a range of projects involving significant Cape buildings and landscapes. Mike's primary interest and research focus lies in adaptive reuse and exploring ways in which meaning can be layered and interpreted in changing contexts.

NARRATING THE LAYERS OF HISTORY: EXPLORING TEMPORAL CHANGES AND PRACTICAL REALITIES IN SCHOOL BUILDING RENOVATIONS

MERIC ALTINTAS KAPTAN
ISTANBUL TECHNICAL UNIVERSITY & TU DELFT

ASLIHAN UNLU
ÖZYEĞIN UNIVERSITY

ABSTRACT

This contribution explores architectural renovations of selected school buildings in Amsterdam from various periods within the Modern Era, each designed by different architects. It entails a thorough investigation of interventions spanning from initial design and construction up to 2010, categorizing them by shared themes and distinctive features. The authenticity and unique attributes of each project are central, influencing the intervention strategies implemented. Emphasis is placed on employing a visual research tool to deeply understand the various interventions shaping the historical narrative. Interventions – harmonizing heritage preservation with contemporary renewal imperatives – are chronologically sequenced, forming the core of the tool.

Methodologically, the research utilizes Amsterdam municipality's digitized data on all buildings until 2010. The selection prioritizes school buildings designated as national or municipal monuments, anticipating access to comprehensive data through official publications and secondary sources. Through a detailed historical analysis, individualized historical trajectories for each building are constructed on a timeline, highlighting technological integrations while uncovering real-life scenarios and practical necessities.

The timeline, more than a chronological record, becomes an intricate storyline and contextual history. 'Breaking points', marking significant interventions, are crucial for understanding transformative changes impacting perception, utilization, and adaptation to contemporary requirements. Integrating textual materials, action descriptions, and analyses of construction documents and technical drawings, the timeline provides a comprehensive representation of the buildings' evolutionary journey.

In conclusion, the study proposes a multi-layered, time-adjusted monitoring dashboard to track architectural renovations. The devised flexible timeline functions as a record-keeping instrument, a streamlined information tagging system, and an integrated visual overview. This chronological data registry synthesizes different information layers within a broader historical context, thus assisting the exploration, structuring, and understanding of the complex building transformations. By complementing the documentation, archiving, and analytical processes, it could potentially serve as a forecasting tool to regulate in future actions in heritage management and planning.

1. INTRODUCTION

Architectural renovations of historic school buildings present a compelling intersection of conservation and contemporary adaptation within the urban landscape. Prior to renovation planning and design stages, it is fundamental to obtain a comprehensive overview of past interventions and analyze the current condition.

Information visualization aims to uncover the underlying structure of extensive datasets by employing graphical elements to represent objects and relations. This process involves substantial schematization, which discards the specificity of objects and 'reduces' data, to extract patterns across their characteristics.[1] Employing a timeline as a research, exploration, and analysis tool is essential, as it offers a visual representation of a building's historical evolution. This approach resonates with the insights derived from Grandjean's[2] exploration of data visualization in historical contexts, which underscores their pivotal role in effectively conveying historical narratives and, moreover, as heuristic tools for exploration and analysis. In contemporary historical perception, the timeline serves as a unique graphical embodiment of history, representing and quantifying chronological connections while encapsulating the essence of the historical era.[3]

Timelines, as visual and art-based data collection methods,[4] are indispensable tools in constructing narratives, conceptualizing and understanding personal or collective histories within qualitative research methodologies, serving as both final outputs and catalysts for additional reflection.[5] Utilizing timelines for retracing individual journeys or documenting narrative interviews demonstrates their potential in comprehending a building's historical evolution and transformative moments, akin to how a physician uses a patient's medical history for diagnosis and treatment planning.

In the context of this study, timeline - as a visual research tool - facilitates a chronological exploration of a building's history, enabling researchers and viewers to navigate through its temporal layers and uncover patterns or transformations that might not be immediately apparent from textual sources alone – by simplifying the complex historical information.

This approach ensures the building's perpetual evolution is presented comprehensively, with the integrity of meaning intact. The timeline functions as a catalyst for researchers and decision-makers in interpreting and evaluating past interventions through documentation and analysis. To transcend the limitations of a purely linear historical flow, and to enrich the timeline with multiple informative layers, approaches relating to building systems and layers, and conservation and renovation practices have been examined.

A decisive complement to this chronological record is identifying the 'where' or 'what' of the intervention, by specifying the object, fabric, or layer undergoing modification.

In construction and architecture, interpreting a building as a complex system involves analyzing how its components interact, from exterior to interior, including connections to service systems and municipal infrastructure, evaluating their performance over time. The conceptualization

of building performance through a systems approach was established and put into practice during the early 1970s by the US National Bureau of Standards.[6] Since then, it has been the subject of discourse in numerous publications and has evolved into a foundational framework for built environment studies.

Aligned with this perspective, the principle of 'layering' highlights the varied rates of change among a building's constituents, reflecting their service lives. The concept of shearing layers illustrates the dynamics of change and adaptation within buildings. Brand suggests that buildings have different layers (i.e., site, structure, skin, services, space plan, and stuff), each with its own pace of change, ranging from rapid shifts within short periods to potentially enduring changes over time.[7]

Brand's concept has been highly influential, extensively utilized and reproduced in the field. The relationship between the layers and temporality is revisited in various sources, with 'replacement cycles' being reinterpreted and re-estimated for different recurrence intervals.[8-9]

A further aspect to support and enrich this chronological record is identifying the rationale behind the intervention, specifically the 'why' or 'what for' in relation to the building's storyline and contextual integrity. The issues, deficiencies, or requirements addressed can be incorporated as an additional layer into this historical narrative.

International literature regarding building conversion strategies reveals diverse findings across various contexts and dimensions. Broekhuizen[10] suggests that a commonly employed standard model for conversion delineates four intervention levels applicable to existing buildings: physical/material change, spatial change, alteration of building volume, and functional adjustment. In the Atlas of School Building *(Scholenbouw Atlas)*, Boekhuizen outlines nine strategies grounded in material-spatial criteria for adapting existing schools through physical-spatial interventions, noting partial overlaps among them.[10-11]

Alternatively, from a conservation standpoint and based on impact evaluation, the ERM *(Stichting Erkende Restauratiekwaliteit Monumentenzorg)*[12] has introduced the 'Restoration Ladder' inspired by the Venice Charter, outlining three prioritized intervention levels: preservation/ maintenance, repair, and reconstruction. In implementation, these steps are guided by principles such as minimal intervention, solidity/durability, compatibility, material principle, and replacement with similar materials or techniques.[12-13]

A timeline can therefore be employed as a multi-layered record-keeping instrument, a streamlined information tagging system, and an overview that synthesizes and integrates diverse layers of information within the broader historical context. By facilitating the documentation, archiving, and analytical processes, it has the potential to guide or inform future actions.

2. METHOD FOR EXPLORING THE LAYERS OF HISTORY

For the selected case-study buildings, an initial review and examination of the construction and environmental files available in the archives of the Amsterdam municipality were conducted. Interventions were depicted

on timelines based on the years of relevant documents, establishing a chronological narrative for each building and highlighting pivotal moments in its history. The development of these timelines involved consulting the image bank of the Municipality of Amsterdam City Archives *(Gemeente Amsterdam Stadsarchief)*[14] and other supplementary sources. The primary objective of this stage was to clarify each building's narrative by synthesizing information sourced from various outlets, including primary construction files and additional reference materials.

During the data collection phase, interventions identified were documented as textual descriptions, referred to as 'action descriptions' in this study, and compiled into separate datasheets using Excel for each case-study building. The organization of these interventions were essential, employing an analytical approach to identify shared themes. Initially, the location of each intervention was determined, following a two-level categorization, inspired by the building systems approach and 'layering' principles. This grouping describes the part of the building affected by the intervention. The second category, also structured into two levels, explores the impact of the intervention concerning updates and enhancements to the building condition, addressing the rationale or objective for improvement. Given the diverse nature and level of detail in the action descriptions, a thematic categorization of interventions was needed. The action descriptions themselves guided the creation of these shared themes, implemented through an iterative process. Consequently, the identified action descriptions for each building were organized under a three-level hierarchy. These additional organization and categories are expected to further enhance the visualizations for different purposes.

To test and design the applicability of additional layers to the historical narrative, a secondary timeline was created based on the identified significant intervention times (i.e., 'breaking points') and the concept of shearing layers. Brand's renowned diagram was employed as a data-driven label to visually link the documented interventions and their associated shearing layers to the timeline. Each line running from the inside out represents a different building layer, similar to the original diagram. Different colors indicate different temporal cycles and periods, expanding the chronological record with supplementary information, addressing the 'where' or 'what' questions, and illustrating the temporal sequence of these interventions across the various layers. Additionally, icons were integrated into the historical narrative to provide a third informational dimension, which addresses the 'why' behind the intervention.

3. COMPARISON OF CASE-STUDY CARIABLES

An essential criterion for selecting the case study buildings is the availability of specific data related to the structures and interventions. Furthermore, the national or municipal monument status of these buildings is significant, as it ensures easier access to a broader range of information. Through detailed historical analysis, the research aims to uncover temporal similarities or differences, distinct historical processes and characteristics, among the

14. Stadsarchief Amsterdam [Amsterdam City Archives], accessed December 12, 2023, https://www.amsterdam.nl/stadsarchief/amsterdam-city-archives/

selected architectural case studies: *Openluchtschool*, 1930; *Buitenveldertse Montessorischool*, 1975; *SBO De Kans*, 1952; *Amsterdamse Montessorischool en Willemsparkschool*, 1983; and *5e Montessorischool*, 1931.

Of the five selected school buildings, one holds national monument status, while the remaining four are municipal monuments. These buildings are situated in various parts of the city, some within protected areas.[15] The Open-air school, located within a nationally protected cityscape, has undergone six notable interventions. Positioned towards the north of the city, the Buitenveldert Montessori School has undergone one major intervention. SBO De Kans is situated within a reconstruction area of national importance and has experienced three notable interventions throughout its historical timeline. The Apollo Schools, situated within a nationally protected cityscape, consist of two independent structures and have undergone three notable interventions. Finally, the 5th Montessori School has experienced two notable interventions.

4. FINDINGS

The study has focused on developing and testing the multi-layered timeline through a selective exploration of five distinctive Amsterdam school buildings, driven by the municipality's comprehensive digital database. Leveraging these documents, construction timelines were delineated, creating detailed chronological accounts of each building's evolution. This methodical approach highlights the significance of utilizing available digital resources and establishes a crucial foundation for temporal analysis within the broader context of the study.

As anticipated, each building exhibits distinct timelines featuring varying numbers of 'breaking points,' equivalent to significant interventions. These timelines present diverse levels of detail in terms of information, reflecting different life spans. Various aspects, issues, or narratives take prominence for each case, highlighting the uniqueness of these buildings. The interventions, regardless of their technical or practical nature, are intricately connected to the individual stories and contextual history of each building.

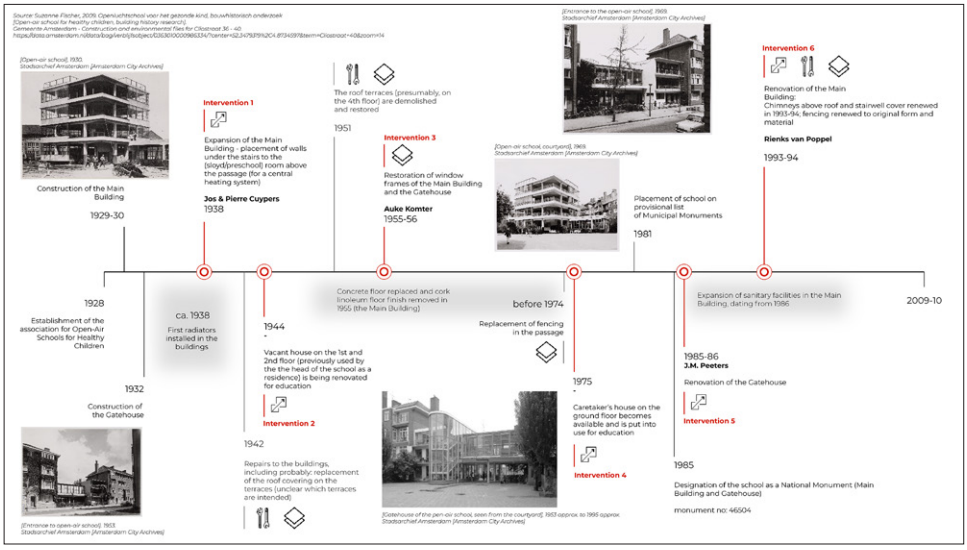
Illustrated in (**Fig. 1**) the Open-Air School, one of the oldest school buildings among the selected cases, features a particularly informative timeline. This data richness can be attributed to the building's construction year and age, its national monument status contributes significantly to the wealth of available information. In contrast, SBO De Kans, depicted in (**Fig. 2**), presents a less-dense timeline, indicating either fewer interventions or less available information. Notably, identifying pivotal moments relies on both data availability and subjective judgments. Some intervention points marked on the timeline, such as roof terrace repairs, were noted from written documents rather than architectural drawing, emphasizing the subjective nature, flexibility, and inclusivity of the timeline approach.

The multi-layered, time-adjusted monitoring dashboard (**Fig. 3**) illustrates alterations and interventions in the Open-Air School's historical process, associating them with building layers through data-driven labels. The relevant years' interventions are indicated in the color-coded layers. Nevertheless,

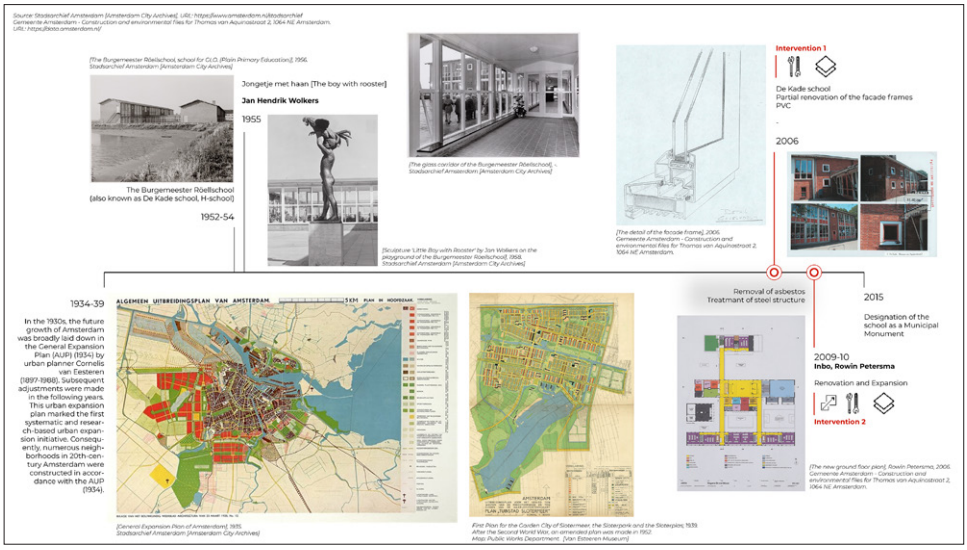
15. Gemeente Amsterdam – Interactieve kaarten [Municipality of Amsterdam – Interactive maps], accessed January 18, 2024, https://maps.amsterdam.nl/cultuurhistorie/

the limited number of documented interventions makes pattern identification challenging, rendering forward predictions based on a singular timeline infeasible. The temporal sequence for a single case building should be refined by incorporating data from multiple cases to reveal observable and reliable patterns, thereby reinforcing the 'estimated' replacement cycle of layers with real-life data.

An overall detailed analysis of intervention locations highlights the 'Building Envelope' (skin) as a significant focus area. Additionally, the interventions are primarily designed to enhance inhabitability, functionality, and technical compatibility of the buildings.



While certain topics may appear prominent in this discussion, they do not imply a quantifiable measure or hierarchical ranking of intervention importance. Rather, their prominence reflects broader relevance within the context of architectural renovations and their potential representations on timelines. In this study, they serve to explore the feasibility of incorporating additional layers onto timelines, potentially enriching historical narratives. Through color coding and iconography, these categories could be integrated into timelines for a more nuanced and comprehensive understanding of a building's history.



5. DISCUSSION

The presented study, which examined specific case studies to develop a systematic approach to understanding intervention processes, constituted a precursor exploration to the doctoral thesis. It utilized authentic data derived from real-life scenarios to consolidate disparate information layers through a temporal lens. Further case studies would facilitate the implementation of data-driven approaches to pattern recognition and prediction.

Each building and renovation project is unique, influenced by a complex interplay of its historical significance, structural condition, functional requirements, and societal implications. Variations in data availability and information quality further complicates the examination of real-life scenarios. Therefore, a holistic yet refined analysis is crucial to comprehend the multifaceted nature of architectural interventions and their implications.

Visualized historical layers facilitate understanding of past uses, architectural alterations, and adaptations, thereby informing decision-making processes in conservation, restoration, and adaptive reuse projects. Analyzing patterns and trends across different renovation projects reveals common themes, challenges, and opportunities within the field and practice. This enables the development of best practices and guidelines for sustainable heritage management, ensuring the long-term preservation of built heritage for future generations. The proposed multi-layered, time-adjusted monitoring dashboard could potentially be a valuable tool for predicting forthcoming interventions, aiding systematic resource allocation and intervention management planning. Accordingly, it may assist to prioritize heritage management activities, by discerning probable future interventions and forecasting their timing, location, layers affected, and any possible deficiencies based on observed patterns and replacement cycles. In turn,

Construction of the Main Building
1929-30
Intervention 1
Expansion of the Main Building - placement of walls under the stairs to the (lloyd)preschool] room above the passage (for a central heating system)

this could support the planning of technological and budgetary resources for heritage management initiatives.

The proposed dashboard and labelling system can be developed and implemented on a local scale (e.g., neighbourhoods), thereby providing decision-makers with a tool to guide inspection and maintenance efforts. This approach offers a prospective and directional framework for heritage management, aiding the timely surveillance and targeted detection of buildings or regions needing attention. In the context of urban planning and development, the insights gleaned from building timelines can inform strategies for revitalizing historic neighborhoods and integrating heritage conservation into urban regeneration initiatives. Additionally, the utilization of visualized information has been demonstrated to improve decision accuracy and quality, directing attention towards uncertainty, and expediting cognitive processing.[16] Consequently, timelines would contribute to reflection of subjective judgements by prompting enquiry into the relative significance of different elements.

Looking ahead, future research could further explore the potential relationships and correlations between intervention locations, building performance aspects, and thematic categories to inform decision-making processes and prioritize interventions for improved building performance – renovation practices and overall protection. ■

BIOGRAPHY

Meriç Altıntaş Kaptan is a PhD candidate at Istanbul Technical University (ITU), Construction Sciences Program. B.Sc. in Architecture (2015) and M.Sc. in Environmental Control and Building Technologies (2018) from ITU. Between 2018-2019, she participated in an Erasmus+ partnership project entitled "Re-use of Modernist Buildings (RMB)". In 2021, she joined COST Action-MCMH EU as a WG3 member and she was recently involved in the FOMA Forgotten Masterpieces project. Meriç has served as a research assistant in ITU Architecture Department since 2018 and is a Docomomo-TR Technology Committee member. She is pursuing studies at TU Delft as a guest PhD researcher.

Aslıhan Ünlü graduated from Istanbul Technical University (ITU) with a Bachelor's degree in Architecture. She received her MSc and PhD degrees from ITU. In 2003-2004, she was a visiting researcher at Lawrence Berkeley National Laboratory. In 2012-2013 as Fulbright Fellow, she was visiting professor at Roger Williams University. She received her "Full Professorship" in 2014. Prof. Ünlü has been the Dean of the Faculty of Architecture and Design at Ozyegin University (OzU) since 2020. She researches sustainable building technologies, façade systems and performance evaluation. She is a member of Association of Architecture Education, European Façade Network and editorial board member of JFDE.

THE WEISSENHOF ESTATE FROM THE POINT OF VIEW OF THE STATE RESEARCH SOCIETY FOR ECONOMICS IN CONSTRUCTION AND HOUSING

EDYTA NAWORSKA
WROCŁAW UNIVERSITY OF SCIENCE AND TECHNOLOGY,
WROCŁAW, POLAND

ABSTRACT

After World War I, the Weimar Republic tackled the housing issue amid challenging economic conditions, constructing new housing estates that set a model for modern solutions. The influx of foreign capital under the Charles Dawes Plan in 1924 fuelled the German economy during the "golden twenties." Public organisations focused on rational housing estates were established and financially supported by city and state governments. On December 14, 1926, the State Research Society for Economics in Construction and Housing (RFG) was founded in Germany. It aimed to conduct research, finance development projects, and support exemplary housing implementations. RFG, which comprised architects, politicians, scientists, and non-profit construction representatives, addressed apartment layouts, materials, technologies, and healthy living conditions. It published special issues on apartment plans, kitchen design, and housing estates, including the Weissenhof estate. Despite initial admiration, negative opinions were voiced, criticising design flaws and the creators' attitudes towards housing and residents. The report highlighted design errors affecting residents' comfort and safety. Critics expressed astonishment when comparing the architects' designs with the final outcomes. Eventually, the Weissenhof estate was deemed a 'stain of shame' as the Neues Bauen architectural trend faded in Germany. However, the estate, despite its flaws, left an indelible mark on the history of architecture. It marked the beginning of industrial construction methods and a new lifestyle, significantly influencing modern architecture in Europe. Weissenhof, with its imperfections, inspired similar projects and spurred further innovation in housing development, a testament to its enduring influence.

1. INTRODUCTION

On July 23, 1927, an exhibition organised by the Werkbund called "Die Wohnung" in Stuttgart was opened. The exhibition's main focus was an experimental housing estate located on the slope of one of the hills in Stuttgart, consisting of 33 diverse houses: multi-family, single-family, row houses, and detached houses, in which 63 model apartments were furnished. The model homes were built in a record two weeks and showcased new forms, constructions, and a new way of organising living space. Over the following 11 weeks, approximately 500,000 visitors toured the exhibition, mainly focusing on the theme of housing in its various aspects. Prominent architects of the interwar period responded with their designs to the question of how to live and dwell in modern post-war times.[1] The history of creating the experimental housing estate is directly linked to post-World War I state policy, when the Weimar Republic, facing economic difficulties, took action to solve the housing problem. Despite resource exhaustion and the need to pay war reparations, the country began building new settlements that served as a model of modern housing. Thanks to the Dawes Plan of 1924, foreign capital was introduced into the German economy. The beginning of the plan is considered the inauguration of the so-called "Roaring Twenties." After the end of World War I, many cities came under the rule of social democratic environments, which enabled the implementation of ambitious housing projects for the working masses. In 1926, there was a plan to finance around 1,600 new apartments through funds collected from property taxes and loans provided under the plan. The amendment to the building law introduced in 1925 in Berlin and later in all German cities, aimed to improve housing conditions, which increased the need to construct new residential complexes. The law also defined standards for apartment size, quality of sanitary equipment, lighting and ventilation conditions, and protected tenants from excessively high rents.[2]

During this period, public organisations were established, such as DEGEWO (Deutsche Gesellschaft zur Förderung des Wohnungsbaus), GAGFAH (Gemeinnützige A.G. für Angestellten Heimstätten), and GEHAG (Gemeinnützige Heimstätten Spar- und Bau A.G.), which were involved in the construction of rational residential estates, financially supported by municipal authorities and the governments of individual states. Architects of the European avant-garde at that time emphasised the need for applying strict, scientific methods in designing rational housing. In 1926, the Reichstag passed a law promoting residential construction to counter housing shortages. In the same year, a commission was also established to examine new methods of rationalising and financing construction.[3] [4] [5] [6]

century. The society was officially registered on January 21, 1928, after a year of establishing its regulations. It operated until June 5, 1931, and was dedicated to conducting and financing research on rational construction and supporting model housing projects, making a substantial impact on the field. In its first year of existence, the RFG received 10 million marks from the state for research on housing rationalisation and construction cost reduction. Some Reichstag committees partially implemented the programmes developed by RFG. The structure of RFG included the assembly of members, the administrative council, the expert council, and the management. Working committees developed specific research topics. RFG had 15 such committees, with members consisting of architects, politicians, scientists, and representatives from the non-profit construction sector. Among the members were well-known architects such as Walter Gropius, Ernst May, Bruno Taut, Max Taut, and Martin Wagner, as well as politicians like Marie-Elisabeth Lüders, Ludwig Landmann (Mayor of Frankfurt on the Main), and Riepert. RFG dealt with issues related to the internal layouts of apartments and their surface area, as well as the introduction of new materials and technologies to reduce home construction costs. There were also discussions on the proper orientation of the cardinal directions to ensure rational sunlight exposure in rooms and thus provide healthy living conditions[7].

2.2. SPECIAL ISSUES

The first special issue was published in April 1928 and dedicated to the design of small and medium-sized apartments ranging from approximately 28m2 to 48m^2. The second special issue , published the same year, focused on kitchens. Subsequent issues were centred on the housing estates, which were a key area of focus for RFG, the organisation spearheading these developments.

The issue concerning the Weissenhof estate was released two years after its completion, allowing for identifying flaws in the proposed solutions. RFG conducted inspections on the estate to assess the residents' comfort with the designed buildings. The experimental buildings were completed in August 1927, and the first residents moved in during the winter of 1927/1928[8].

3. POSTULATES AND THEMES OF THE EXHIBITION IN STUTTGART

The exhibition in Stuttgart combined the exhibition with the newly built model estate on Weissenhof hill. Among the 17 invited architects representing the European avant-garde were Ludwig Mies van der Rohe, Adolf G. Schneck, Walter Gropius, Ludwig Hilberseimer, Bruno Taut, Max Taut, Hans Poelzig, Richard Doecker, Adolf Rading, Peter Behrens, Hans Scharoun, Jacobus Johannes Pieter Oud, Mart Stam, Victor Bourgeois, Le Corbusier, Pierre Jeanneret[9]. The idea behind organising the Die Wohnung exhibition combined with the model estate was formulated in a manifesto and programme of the entire undertaking, published in December 1926. This document emphasised that the critical issue in housing construction is to shape the building plan with the current needs of the residents in mind. Housing should be comfortable and practical and occupy as little space as

7. Kononowicz, "Ewolucja osiedla mieszkaniowego we Wrocławiu okresu Republiki Weimarskiej – Księże Małe", 453-455.

8. Bericht über die Siedlung in Stuttgart am Weissenhof, RFG, Sonderheft 6, vol. 1, April 1929.

possible. Therefore, an innovative approach to the functional design of a small apartment was necessary, considering the limited financial resources allocated for its construction, which needed to be optimally utilised. Another important aspect is to change the approach to construction by using new structures and materials. It was noted that construction had relied too long on traditional methods, and failed to embrace processes of industrialisation and standardisation. There was a call for engineers, chemists, and industry collaborate to seek new constructions and materials to find new, rational solutions in construction. One of the main goals of the exhibition was to test existing materials and new constructions proposed by engineers, with a particular focus on the "dry" assembly of buildings. This system allowed for the transfer of the construction process from the building site to the factory, enabling faster occupancy of homes. It was emphasised that the key aspect of industrialisation must be the standardisation and normalisation of all building components[10]. The exhibition programme did not emphasise any formal characteristics of the new architecture. The presented apartments were to serve as prototypes for mass production. Architects aimed to prove that industrialisation did not have to lead to the complete standardisation of houses and the loss of individuality. The choice of the terrain on the hillside provided a magnificent view of the city. The spatial layout involved alternative placement of single-family housing flanked by high-rise buildings, culminating in multi-family housing at the top of the hill.Ludwig Mies van der Rohe and Peter Behrens designed rental apartments in larger buildings, while Jacobus Johannes Peter Oud, Adolf G. Schneck, and Mart Stam proposed row houses[11] [12]. The estate also featured semi-detached houses designed by Le Corbusier, Pierre Jeanneret, and Josef Frank. The remaining projects focused on diverse, more exclusive single-family homes that initially did not fit in with the estate concept. In the preliminary analysis report by RFG, it was noted that some apartments were unsuitable for most of the population because their area exceeded typical sizes for small and medium-sized apartments. Only the buildings designed by Behrens, Mies van der Rohe, Oud, and Stam were thoroughly evaluated. Critics saw the potential for serial prefabrication in them at relatively low costs. The other projects were not analysed because they were considered unsuitable for economic mass production and were of no interest to the RFG. However, all houses were thoroughly analysed regarding construction methods, structure, and materials. The RFG special issue contained not only the report materials of the organisation's scientific committee but also excerpts from press and specialist publications, book excerpts, and statements from the estate architects[13].

4. COMMUNITY EVALUATION

4.1. CRITICAL OPINIONS

Despite receiving sponsorship from the RFG, the settlement did not escape scrutiny from experts at this esteemed organisation. Their negative opinions, backed by their extensive knowledge and experience, mainly focused on the simple roofs and the creators' approach to housing and residents.

Franz Hoffman-Johannisthal, a renowned architectural critic, wrote in Die Bautwelt (1927, Issue 41) that "these houses are already being rejected by sensible people today, let alone after 10 years...". The flat roofs of single-family houses, often used as gardens, were not just a matter of design, but also practicality. They were criticised for the high maintenance costs of such a garden (a traditional ground-level garden was much cheaper) and issues with leakage due to imperfect construction quality. The first residents, mainly scientific workers, were among those to experience these issues firsthand. Dr. Grünbaum's (RFG) report from a visit from July 9 to 14, 1928, titled "Who is the settlement built for?" indicated that the Weissenhof buildings were not just unsuitable for children, but even hostile to them. The location of the settlement outside the city was intended primarily for large families, but there was a lack of children's rooms, and there was no space for cribs in the parents' bedrooms. Low railings and lack of window protection posed a danger to the youngest, leading young women to avoid pregnancy until they moved out of Weissenhof. Franz Hoffurun-Johannisthal criticised the location and dimensions of the windows. For example, in the Ouda project house, the windows were set too high up, making it impossible to open them for ventilation. The author pointed out problems with the partition walls used by van der Rohe, which became unsightly and caused noise. Additionally, many visitors needed to understand the concept of openings in the walls and asked about the possibility of adding doors. Hoffurun-Johannisthal also criticised the lack of windows in the child's room designed by Professor Behrens, which prevented natural ventilation and compromised the safety of children who could wander into the garden unnoticed at any time of day or night. The RFG's B8 report contained detailed observations regarding the usability for domestic use. The document highlighted, among other things, the lack of a pantry.

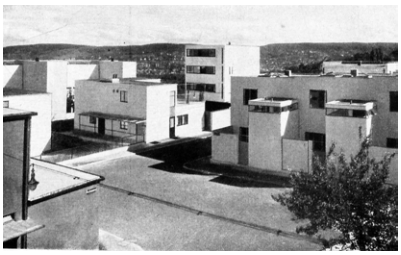
Furthermore, the kitchens were located in the south, forcing housewives to run to the cellar for supplies. The design was commended for its foresight in including spaces such as a laundry room, storage room, and drying. However, it was noted that their potential could have been more utilised due to poor placement. The unfortunate layout of the apartments was criticised, where the bathroom sink was placed directly under the window, which could lead to discomfort for its users, and there was a risk of the pipe freezing. The magnificent balustrade made of nickel pipes, which left almost no marks when touched, was admired. A common issue in many houses was the location of the windows - they were placed so high that it was difficult to access them from both the outside and inside for cleaning purposes. Opening them often required absurd preparations, such as jumping over the sink and climbing onto a chair taken from the bedroom and placed in the bathtub. As accurately noted in the analysis: "Anyone moving into these houses must purchase a window cleaning subscription from a window cleaning company, as it cannot be expected that the housewife or maid will perform this acrobatic task." Le Corbusier and Pierre Jeanneret's house was the most expensive and farthest from the original goal of designing housing for people with low to medium incomes. Although the RFG report did not

focus on this particular building, experts did not fail to mention the house designed by the famous architect. The design flaws were harshly criticised, beginning with the entrance to the house, leading to its central heating; as written, it was a repulsive sight. The dangerous staircase was highlighted, from which falling was easy. Negative comments were made about the chimneys running through the centre of the rooms on each floor. According to the report, dividing rooms with full-height walls was a luxury for Corbusier. The designer used concrete walls 1.6m high - the rooms were interconnected, causing food odours from the kitchen and noise from other rooms to reach the main living room. The beds on wheels (which could be stored in a particular niche when not in use) were criticised, pointing out the lack of comfort for the user in sleeping 30 cm above the floor. The location of the sink at the end of an undecorated corridor was deemed senseless. The windows in this corridor were compared to those found in refrigerators or warehouses. Walter Gropius's plans for house number 16 were considered thoughtful but could have been more impressive. Safety concerns for the youngest users resurfaced - the railings were designed in such a way that it would have been easy to fall off the stairs. The plywood exterior doors were considered a misguided idea. The balcony doors could have been better made. The housewife praised the solid terrazzo floor, while the floor covering was deemed too delicate[14].

4.2. STEP INTO MODERNITY

The advocates of the housing development emphasise the modernity of the adopted solutions and endorse a modern lifestyle - a garden on the terrace is not only a place for relaxation and drying laundry but also equipped with gym equipment - after all, a healthy mind results in a healthy body. The numerous existing extensions to the buildings can be used in various ways to meet diverse needs. Residents decide for themselves what they need and what has a real influence on their living space. A small kitchen does not have to be an uneconomical solution - a smaller kitchen means short distances, as well as careful and thoughtful selection of furniture. This room also ceased to be the most important for the housewife - 'Today, the homemaker wants to finish her work as quickly as possible (...) the saved time can be used for better things.' There was a shift in mentality from the typical German 'Hausfrau', to that of a working woman aware of her social utility[15]. Bedrooms also do not necessarily require a large area - it is a matter of good room organisation and placing appropriate furniture. The room furnishings are simple, unpretentious, and inexpensive - enabling mass production. Undoubtedly, the design of the houses and their arrangement were a significant step towards modernity – although not all residents were ready for it. As the report states: 'housewives from Weißenhof settlement have both praise and complaints. There were no indifferent comments[16].

4.2. CONSTRUCTION EXPERIMENT



Although experimenting with new materials and construction methods was considered a positive development, some critics raised concerns that the

Figure 2. Weissenhof Estate, authors of houses from left: Oud, Le Corbusier and Jeanneret, Gropius and once again Le Corbusier, illustration from *Bericht über die Siedlung in Stuttgart am Weissenhof*, RFG, *Sonderheft* 6, *vol.* 1, *April* 1929, 12.

Figure 3. Weissenhof Estate, Oud's houses under construction, illustration from *Bericht über die Siedlung in Stuttgart am Weissenhof*, RFG, *Sonderheft* 6, *vol.* 1, *April* 1929, 102.

practicality and cost-effectiveness of these innovations were uncertain and may only reveal themselves over time. Some reports highlighted technical flaws and execution problems in the construction of buildings in Weißenhof, which could impact on the overall quality and functionality of the homes. The cost of implementing new construction methods, materials, and designs may have been higher than traditional methods, raising numerous questions about the economic feasibility and accessibility of such innovations for the average population.

Critics rightly note, however, that these were new solutions - previously unused – and therefore, it is unsurprising that the time required for completion extended beyond the initial assumption and builders faced shortcomings - after all, it was their first encounter with this technology.

5. SUMMARY

Critics in the RFG often expressed surprise when they compared the exquisite drawings and designs by renowned architects with the final results. As the architectural trend of Neues Bauen fell out of favour in Germany, the Weißenhof Estate was harshly criticised and branded a "stain of shame"[17]. Nonetheless, the estate symbolises two profound shifts - the adoption of industrial construction methods and a glimpse of a new way of living. Its significant impact on the evolution of modern architecture in Europe cannot be understated. Intended as the dawn of a fresh era unbound by traditional construction practices and a catalyst for a new lifestyle, Weißenhof, despite its imperfections, influenced and inspired the development of other similar projects. ■

BIOGRAPHY

Edyta Naworska is an architect and a doctoral student at the Faculty of Architecture of Wrocław University of Science and Technology. She is conducting her doctoral research on "The significance and impact of state policy on residential construction in Wrocław, including the activities of housing cooperatives in the interwar period," under her advisor, Dr. Eng. Arch. Jadwiga Urbanik and Dr. Jerzy Ilkosz. In 2021, she completed her master's in Architecture and Urban Planning at Wrocław University of Science and Technology. She works at the Wrocław-based architectural firm PORT, specialising in residential architecture.

NOTABLE RENOVATIONS IN ORDINARY CONTEXTS

DANILO MATOSO MACEDO
CHAMBER OF DEPUTIES, BRAZIL

ANA CAROLINA PELLEGRINI
FEDERAL UNIVERSITY OF RIO GRANDE DO SUL, BRAZIL

ABSTRACT

Retrofitting, remodelling, rehabilitation, refurbishment, reconstruction, and reuse encompass a wide range of design operations in existing buildings. Although these terms may appear vague as concepts, they all entail a departure from, or even a transcendence of, classical canons of restoration. Nevertheless, all these terms could be unified under the umbrella of "renovation". Renovations, in their turn, are as common as they are unjustly undervalued by contemporary criticism and historiography. Unlike entirely new buildings, which establish a form of order within a given reality, and unlike restoration, which aims to re-establish some authentic or ideal state (not always clearly determined), renovation is rooted in conservatism but fuelled by transformative original intent. Renovation treats the existing text as a pretext and interacts with it more freely than restoration, involving actions such as cutting, adding, pasting, and remaking. A renovation begins with an examination of the pre-existing condition and a practical need for the sustainable utilisation of built infrastructure. Demolition and disposal would not only generate more solid waste but also presuppose an unsustainable consumption of natural resources for reconstruction. Tailored to diverse requirements for permanence, and primarily economic purposes, the renovation process dispenses with a specific grammar or predictable outcomes. Renovation is liberated from a subordinate role, as it integrates pre-existing elements into a new reality where to paraphrase Riegl, novelty becomes a heritage value capable of surpassing antiquity. In this way, this session gathers contributions addressing architectural projects capable of stimulating academic discourse on this common yet frequently overlooked design operation: renovation.

1. INTRODUCTION

Intervening in pre-existing architectures is a design operation that usually presupposes a hierarchy of values. Since the Venice Charter, the prevailing stance has been that the new architecture should not rival the existing structure, which under no circumstances should lose its role as the protagonist. This session, however, aims to explore a different approach to the subject, focusing on notable renovation operations carried out on ordinary architectures.

2. OUT-OF-TIME ARCHITECTURES

It is common to attempt to regulate or evaluate new architectures designed to transform or co-exist with older ones by using criteria similar to those adopted in restoration procedures—such as distinguishability or reversibility. Both address materiality and are related to plasticity and construction techniques. The greatest concern seems to be that the newer architecture may harm or compromise the enjoyment of the older, and seldom is the opposite considered: that, at least since the Aloïs Riegl's Modern Cult of Monuments[1], novelty has also been recognised as a value of heritage and may even surpass the importance of antiquity.

Unlike restoration, renovation does not have a specialised field of knowledge, which exacerbates the misunderstanding between purpose and prescription. This is a more sensitive issue when dealing with a listed building, which may require the proponent of the new architecture to comply with the recommendations of the heritage protection authority. Such indications generally also—and primarily—follow the content of those concerning restoration procedures.

"*Tempus edax rerum*"[2]. Ovid's phrase expresses the inexorable nature of time and its effects. However, the concern related to the deterioration of living beings and their creations predates the Roman poet. Since the myth of Zeus restoring his siblings who were devoured by Cronus, there have been numerous attempts to reverse aging and decay.

The enduring existence of a building implies prolonged exposure to weathering and wear from use, requiring adaptation to cultural, economic, environmental, and social changes. In architecture, resisting the effect of time is generally achieved through two main approaches: restoration or renovation. In the former, the aim is typically to preserve or reinstate past aesthetics and often the original materiality, with a focus on the past. In the latter, alterations in both appearance and materiality are accepted to ensure the persistence or revitalisation of the structure, with a focus on the future.

Preserving architecture, therefore, may require not only conserving it but also adapting it. In some cases, the premise is not "how to maintain" but rather "how to transform" the built environment through an architecture that is chronologically independent of a pre-existing structure and whose level of excellence may surpass that of the former. The design approach presented here considers that heritage value may originate from the new architecture, the new design within the old construction, or the new construction based on the old design, and suggests that architectures detached from a specific

reference time—such as that of a pre-existing building—are capable of conferring new status upon the past.

3. RENOVATED PAST

The design procedure discussed here is far from being unheard of or exclusive to modern times. One of the most recurring themes in the History of Conservation—the Christian basilicas—originated from the adaptation of an ancient typology, the Roman basilica.[3] The ancient Hall of Justice was originally a large, oblong building, typically consisting of a nave, two side aisles, and one or more apses. The side aisles are lower in height to avoid obstructing the high windows in the upper part of the nave, features that were retained in the early Christian basilicas, as observed in the Basilica of Old St. Peter's (A.D. 324) and San Paolo Fuori le Mura (A.D. 385), both in Rome[4].

Dating back to at least the Renaissance, there have been records of architectural commissions aimed at transforming buildings and urban spaces through new projects. In the mid-15th century, in Rimini and Florence, Alberti undertook interventions in medieval churches. In Rimini, he renovated a Franciscan church built in the 13th century with Gothic features. Alberti's renovation aimed to transform the small and modest church into a monument that would attest to the power of Prince Sigismondo Malatesta, who had commissioned the work. The work likely began in 1453, but construction was interrupted due to Malatesta's death in 1468. Although the church remained incomplete, what stands out is the addition of a layer of white stone that covers the main façade and sides, creating a façade mask with regular fenestration that is set apart from the plane of the old façades revealing the materiality of the original building. In Florence, Alberti's intervention took place in a Dominican church begun in 1279 whose façade remained unfinished until the mid-15th century. The completion project was commissioned between 1458 and 1460 by Giovanni di Paolo Rucellai, an important Florentine patron (in whose residential palace Alberti also carried out a renovation project). Through his design, Alberti aimed to harmonise the pre-existing characteristics—such as part of the ornamentation, the step between the heights of the naves, and the large central oculus—with rigorous geometric principles of composition. The result is the famous frontispiece in light and dark marbles, with a base marked by pointed arch niches and crowned by a triangular pediment, juxtaposed like a scenography against the previous façade.[5]

Throughout the history of architecture, the conversion of buildings from Ancient Rome into churches was not limited to transforming basilicas. Other examples include the conversion of the Roman Pantheon into the Church of Santa Maria dei Martiri in 608[6] and the Mausoleum of *Santa Constanza* into the Church of *Santa Constanza* in 1256[7]. In the 16th century, Pope Pius IV commissioned Michelangelo to convert part of the ruins of the Baths of Diocletian into the Church of *Santa Maria degli Angeli e dei Martiri*.[8] This may be considered a radical programmatic transformation enabled by interior design, as the church nave would occupy the space previously reserved for the *Tepidarium*. While the façade retained the appearance of a ruin, the

interiors underwent restrained intervention. The dividing walls were smooth, and colours used sparingly, enhancing the monochromatic vaults and the pre-existing columns of reddish granite. The current state of the church has, therefore, been greatly altered compared to the 16th-century intervention, as the walls were decorated in the Baroque style by Luigi Vanvitelli in 1749. (**Fig.1**)

Previously, around 1539, Pope Paul III commissioned Michelangelo to transform the degraded public area on Capitoline Hill into a civic centre befitting the papal capital. The space had already undergone several modifications since Antiquity and featured two pre-existing buildings of different eras and appearances. Michelangelo revamped their façades, adopting the same formal language for both. However, the work had not yet been completed at the time of his death. Their completion was overseen by Giacomo della Porta, while the fundamental construction of the third palace, appropriately named *Palazzo Nuovo*, was initially led by Girolamo Rainaldi and later by his son, Carlo Rainaldi, who completed it in 1653.

The Palladian example of renovation refers to the typology from Antiquity described at the beginning of this section. It pertains to the project for the Basilica in Vicenza. Records indicate that a communal palace existed in the city as early as the 13th century. Over the following two hundred years, a series of incidents necessitated repairs and adaptations to the building. After a severe fire in 1444, the structure was reconstructed under the direction of Domenico da Venezia and was renamed *Palazzo della Ragione*. Construction began in 1451 and was completed in 1460. After undergoing embellishments by Tommaso Formenton between 1481 and 1496, part of the west façade collapsed, prompting other architects to provide consultancy on a new reconstruction. Over nearly five decades, several renowned architects submitted their proposals until Andrea Palladio's design was chosen. Work commenced in 1549 and continued throughout the late 16th century. Palladio died in 1580 and did not live to see his work completed, which occurred around 1617.

As seen, the co-existence of projects conceived by different architects and executed at different periods in the same building or plot is far from being considered exceptional or new. On the contrary, the further back in time one goes, the more common the combinations of layers that constitute a single building or complex of buildings become, given the extended time required for their construction. As for the preceding examples, it cannot be stated that they originated from ordinary pre-existing structures, as originally all were buildings endowed with some degree of monumentality. However, all cases had their significance enhanced and came to be featured in the books of architectural history thanks to out-of-time interventions, as seen more recently with the work of Carlo Scarpa in the Castelvecchio Museum and the Querini Stampalia Foundation[9], or of Daniel Libeskind in the Jewish Museum and the extension of the Military Museum of Dresden[10]. (**Fig. 2; Fig. 3**)

Lina Bo Bardi, a contemporary of Scarpa, carried out a remarkable renovation in an ordinary context in Brazil. Alongside the collaboration of architects Marcelo Ferraz and André Vainer, she conceived the project for

9. Jean-Louis Cohen, *O Futuro da Arquitectura* (São Paulo: Cosac Naify, 2013), 424.

the Leisure Complex of SESC Pompeia. Commissioned in 1976, the project involved adapting an existing set of industrial buildings and constructing new modern architectures. Although not institutionally protected, Lina recognised that the warehouses had value and were suitable for the proposed use, even though they did not fully accommodate it. The programme to be implemented on the site exceeded the space available in the pavilions, and therefore part of the activities was allocated to new buildings to be constructed in the free area of the L-shaped plot, which is crossed by a watercourse and designated as a non-buildable area. The pool, sports courts, changing rooms, dance studios, and a cafeteria were distributed between two reinforced concrete towers with no coating, utilising *béton brut*, and connected by walkways suspended over part of the wooden deck that now covers the pre-existing watercourse. In addition to these new volumes, the architect envisioned a third structure: the cylindrical water tank tower, referencing the factory's destroyed chimney. The warehouses accommodated a restaurant, theatre, library, exhibition and performance areas, as well as workshops for ceramics, tapestry, painting, woodworking, and more. SESC Pompeia was an immediate and enduring public success. Not only was the architectural intervention of undeniable quality, but the community's engagement was also extensive and enthusiastic.[11] In 2015, the National Institute of Historic and Artistic Heritage (IPHAN) listed the complex as a heritage site. (**Fig. 4**)

4. RENOVATED AUTHENTICITY

Admitting renovation as a viable approach to heritage intervention is a controversial stance. For many, renovation carries the stigma of being a secondary design endeavour, diverging from high culture and operating outside clear rules and objective parameters, as supposedly exclusive to the field of restoration.

Regarding the prescriptions on how to intervene in architectural heritage, the Charters of the International Council on Monuments and Sites (ICOMOS) have become *de facto* dogmas in the field of restoration — and often also in renovation projects. These documents have become the preferred tools of the hermeneut on duty, who are willing to conveniently interpret the precepts of these writings, whether to justify their own practices or to discredit those of other professionals (especially those supposedly external to that field).

The prescriptions of the Venice Charter—the reference charter to this day—may appear cohesive, but they present contradictory principles, a natural result of the need for consensus in broad agreements that originated them[12]. For example, while Article 9 states that restoration "aims to conserve and reveal the aesthetic and historical values of the monument and is based on respect for the original material and authentic documents", Article 11 emphasises that "valid contributions from all periods to the building of the monument must be respected, since unity of style is not the aim to be sought in the course of restoration"[13]. It is therefore up to the interpreter to decide what constitutes a restitution of the "original material", based on "authentic documents", and what qualifies "valid contributions" from the historical trajectory of the work.

13. "The Venice Charter." Icomos — International Council on Monuments and Sites, 1964, https://www.icomos.org/en/participer/179-articles-en-francais/ressources/charters-and-standards/157-the-venice-charter.

Such apparent ambiguity lends itself well to criticisms of interventions in cultural heritage, depending on the perspective of those articulating them.

"Criticism" is a key term in the dialectical logic underlying the Venice Charter, which requires an interpretative stance from those involved in the work. It serves as an analytical tool, not a dogmatic manual. After all, like all architecture, a restoration or renovation project involves positioning oneself relative to a pre-existing reality and a material, political, economic, and social context, which is always contradictory.

In "Parallel Lives", Plutarch (46-120 AD) recounts the "Ship of Theseus Paradox". The Athenians are said to have preserved the hero's ship for centuries, and over time "they removed the aging wood and replaced it with sturdy planks, fitting them to the others in such a way that, for philosophers, this ship provided an apt example for discussing the 'growth argument,' with some arguing that the ship remained the same and others that it was no longer the same"[14]. In this context, defining what constitutes "respect for the original materiality" of a built cultural asset is vague. Similarly, the notion of "authenticity" to be recovered or maintained through restoration work remains fluid.

Renovation is also often associated with disfigurement, frivolity, and lack of commitment, and is generally attributed to economic and utilitarian concerns—as if these were lesser motivations. Regarding the issue of authenticity, some argue that renovation produces falsely new and falsely old outcomes, leading to the irreparable loss of the original.

Building, restoring, or renovating are human actions carried out through design and, therefore, imbued with explicit and implicit intentions and contradictions. The confrontation and comparison of different ideas and solutions to achieve new responses is a common practice in architectural design. There are no easy or single truths to guide any design process beforehand in an unquestionable way. Designing a new building, as well as proposing its restoration or renovation, is an open task with results that are not entirely predictable in advance. Fickleness, instability, contradiction, and the adoption of criteria for continuous transformation are inherent to the architect's profession and inevitable when it comes to intervention in built heritage.

Preservation actions regarding heritage are ambivalent because, to conserve, they must transgress and defy chronology. They counteract natural decay, helping to create an apparently ordered cosmos in contrast to the inherent chaos, allowing memory and contemporaneity to coexist within the same building.

Unlike restoration, which aims to return a building to an authentic or ideal state (not always clearly determinable), renovation is based on a conservative foundation but has a transformative purpose. It could be argued that renovation possesses an ambiguous character since its motivation is twofold: to preserve elements of the pre-existing structure(s), in which value is clearly recognised, and to achieve a new form, resulting in renewed plasticity, spatiality, and/or materiality. However, the term "ambiguity" implies doubt, uncertainty, imprecision, and misunderstanding, often suggesting fragility. In light of this, it seems more appropriate to

speak of dialectics, as the dialogic method acknowledges and embraces complexity and counterpoint, thus indicating a strength that, from a Platonist perspective, is integral to the process of seeking truth.

Undoubtedly, these issues warrant further study and exploration, free from prejudices, to advance the field of disciplinary culture and achieve new perspectives, as "dwarfs standing on the shoulders of giants".

> *To assert that something is wrong or false, or that it results from falsification, one must have a clear notion of what is correct, true, or authentic. Naturally, there are different levels of truth and various methods to verify whether something is the case.*[15] ■

He has taken on the role as Architect at the Chamber of Deputies since 2004, working on the preservation of the National Congress Palace and the technical documentation of the building. Furthermore, he has designed various built works in Belo Horizonte and Brasília and was the Co-founder (2007) the Docomomo Brasília Chapter, which he chaired until 2011. Additionally, he authored numerous articles and books on architecture and is the founder and editor of the Architecture and Urbanism magazine MDC <www.mdc.arq.br> (2006-2012).

Ana Carolina Pellegrini holds a graduate degree in Architecture and Urbanism (UFRGS, 1999), a Master's in Architecture (UFRGS, 2003) and a Ph.D in Architecture (UFRGS, 2011). She is also a professor at the Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil and teaches both undergraduate and graduate courses and coordinates the Architecture Research and Graduation Programme – PROPAR; her research explores the themes "out of time architectures" and "design as heritage"; she has articles published on Brazilian and international journals and has participated in several seminars and conferences in Brazil and abroad; she has taken part in all International Docomomo Conferences since 2010.

A CHURCH CHANGES CONFESSION – A TRANSFORMATION PROJECT WITH AESTHETICS BETWEEN EAST AND WEST IN MUNICH (1980-1995)

KORINNA ZINOVIA WEBER
INDEPENDIENT RESEARCHER

ABSTRACT

The case study presented demonstrates how a building's architecture was transformed through the influences of different religious communities. The modern "All Saints" Greek-Orthodox Church in Munich was originally a Catholic church built in the 1920s. It was converted to its present appearance starting in 1993. The Catholic church was planned as a two-stage construction featuring a lower and an upper church situated at the expanding city border of Munich. The design adhered to the simple aesthetics of classicistic modernism. However, due to the world economic crisis in 1929 and the Second World War, only the lower portion was completed. In the 1980s it was offered to the growing Greek-orthodox community of Munich, which was in need of a church. The Greeks quickly became the primary users of the building, despite its relatively poor condition. As a result, the construction of a new church was discussed with the Catholic church, which owned the site.

The project history for this new Greek-Orthodox Church illustrates how various actors influenced the result. The transformation was mostly financed by the Catholic Church and planned by a German Catholic architect. He collaborated closely with the Greek-Orthodox tenants, incorporating some elements of the existing structure to facilitate the process of obtaining the construction permit.

The resulting all-white church reflects how stereotypical Greek architecture inspired the modernist movement from 1930's CIAM to this day. Its appearance is the confluence of diverse narratives: local Catholic architecture converges with Orthodox building language, translating it into a unique architectural amalgamation.

Architecture of (religious) minorities often faces challenges in being seen and recognised in mainstream society. This case study, based on new archival source material, aims to trace a path for proactively recognising and protecting overlooked cultural heritage.

1. THE GROWING GREEK-ORTHODOX COMMUNITY IN MUNICH AFTER 1960

The special relationship between the Greek-Orthodox community and the city of Munich is historically marked by the cession of the Salvator church in the centre of Munich by Bavarian King Ludwig I, in 1828. Following the Recruitment Agreement between Germany and Greece from 1960, numerous Greeks came to Munich as so-called "guest workers". In 1963 the Ecumenical Patriarchate of Constantinople founded the Greek-Orthodox Metropolis of Germany in the former capital Bonn. While the Greek-Orthodox community in Munich was more in need of suitable spaces for the service, the situation became much more pressing when the Salvator church was occupied in 1977 by a splinter group for several years. The Greek-Orthodox Metropolis intensified their efforts to find an alternative church by seeking help from the Protestant Church and the Catholic Church to address their spatial shortage. In this context, the Catholic Church offered the Greek-Orthodox community to co-use the church "Allerseelen" in the Schwabing neighbourhood in the North of Munich, starting from Christmas 1980 onwards.

2. THE CATHOLIC CHURCH "ALLERSEELEN" BY RICHARD STEIDLE 1929

In the early 20th century, the urban area where the Catholic church "Allerseeen" would later be built was dominated by the main building of the Northern cemetery and the working-class district "Alte Heide," designed by architect Theodor Fischer and built between 1919 and 1928. A Catholic pastor bought a piece of land in front of the cemetery in 1923 and transformed the basement of the existing gardener's house on the site into a temporary prayer room. In 1926, the need for a church quickly became apparent. In 1928, architect Richard Steidle designed a two-stage construction featuring a lower and an upper church for the site. Shortly before the construction of the lower church began, the building commission of Munich requested a significant alteration in the design: the flat roof of the temporary section required a "proper" roof. In response, the Catholic Church replied: "It should be noted that a lack of understanding of art was by no means the reason why no roof was originally planned, but the guiding idea was: the more the church gives the impression of a temporary structure - and that is what it is supposed to be - the more likely it is that the church is finished and something whole is created."[1]

This is a specific example of how the City of Munich tried to hinder any tendencies of modern architecture in the cityscape. In the end, the lower church was built with a hipped roof (Fig. 1). However, the construction of the upper part was never realised due to the economic crisis in 1929 and the outbreak of the Second World War that followed soon after. The church survived several bombing attacks during the war, which caused repairable damage.

Eventually however, it lost its significance for its community in the 1950s, when the Catholic parish decided to build a bigger church a few blocks further North on an empty piece of land. As the Allerseelen church

1. Letter from the Church organisation to the city council of the City of Munich, 2nd May 1929, Archive of the Zentralregistratur der Lokalbaukommission München

was rarely used and in poor conditions, the Catholic Church offered it to the Greek-Orthodox community for their services in 1980.

3. THE EVOLUTION TOWARDS A TRANSFORMATION PROJECT

The Greeks quickly became the primary users of the building. As a result, the construction of a new church, replacing that from 1929, was discussed in 1983 with the Catholic Church to fit the needs of the orthodox liturgy better. As the project would be financed mainly by the Catholic Church which owned the site, a local Catholic architect who had previously collaborated with the ordinariate on numerous restorations was commissioned. Initially, a newly constructed church made up of three separate buildings – church, parish office and rectory – was envisioned by architect Robert Brannekämper in 1986, but the idea was abandoned in favour of the Catholic Church, who preferred to alter the existing church rather than demolishing it. The following project was developed in close collaboration with the Greek-Orthodox tenants: the existing volume of the church was elevated with higher walls and a new roof and joined by a new building between the existing church and rectory. The walls of the Allerseelen church have been incorporated into the new construction, not only for nostalgic reasons but firstly to adhere to the law of building on the existing footprint (Fig. 2). In accordance with the orthodox cult's building rules, the altar of the new church is oriented towards the east, which means that the existing entrance was moved further west towards the interior of the site.

When the building permit was requested, the conservation department halted the process to evaluate whether the existing Catholic church from the 1920s could be considered a monument. After several months and following pressure from influential local politicians, the conservation department – without any further research on the building – concluded that the existing church did not represent any further value as a heritage.

4. ENTANGLED REFERENCES: FROM GREECE TO WHITE MODERNISM, ELAPSED POST-MODERNISM AND CATHOLIC ARCHITECTURE

When the architect Robert Brannekämper received the commission to plan an Orthodox church in Munich, he was well aware that the design language needed to be different than that of Orthodox churches in Greece, since the implementation of the construction required the approval of the neighbours and the local building authority.[2] Within this research, three different influences were identified for the unusual shape of the church: Catholic (local) architecture after 1950 in Bavaria, stereotypical "white" architecture from Greek islands and post-modernism. The main components of this building are therefore decoded and related to their references in the following.

The most striking element in the design of the Gr.-Orth. Church Allerheiligen is the proportionally narrow tower, which is unusual for a Greek-Orthodox church (Fig. 3). Free-standing bell towers, if they exist at all, are set lower in volume because of earthquake risks; The Greek cityscape is rather dominated by the domes that are commonly used in

2. Interview with Robert Brannekämper by the author, 03rd June 2022, Munich.

church architecture since the Byzantine period. The bell tower in Munich is more reminiscent of local Catholic Churches from the second half of the 20th century, with sound openings in the upper area.

The main volume of the Gr.-Orth. Church of All Saints bears a striking similarity in form and materiality to the Monastery Church Herz-Jesu designed by architects Alexander von Branca and Herbert Groethuysen in Munich. Brannekämper is familiar with the work of Branca, who he considered one of the "best church designers in Bavaria".[3] Planned and built between 1953 and 1955, the Church Herz-Jesu was part of a monastery complex including a girls' dormitory and was the first church in Munich to be constructed with a raw reinforced concrete skeleton. The geometry with a barrel shell above the main nave and stitch caps above the side aisles can also be found in the Gr.-Orth. Church Allerheiligen, although with a different lighting. The facades of both churches are structured by downpipes at the low points of the stitch caps. This detail in both churches reminds us of the works by architect Hans Döllgast, who was a master to both, Branca and Brannekämper: Von Branca studied drawing with Döllgast, whose "drawing style shaped an entire generation of architects"[4] Brannekämper met Döllgast through his construction work while drawing in the Basilica of St. Boniface in 1962 and Döllgast will remain a "role model for extraordinary drawing art"[5]. It is nevertheless a genuine Munich architectural language in which Brannekämper grew up and by which he was influenced.

Another connection to Brannekämper's architectural language can be found in the work of another Döllgast student, the architect Karljosef Schattner, who, as head of the diocesan building office in Eichstätt, shaped the architectural style of buildings commissioned by the Roman Catholic Church in Bavaria over three decades. Brannekämper is familiar with Schattner's work "from literature" but, according to his own statement, has never met him personally.[6] The combination of deliberately placed, visible dark steel elements in contrast to white plastered surfaces in Brannekämper's designs is reminiscent of Schattner's style. In Brannekämper's design process, the steel elements only appeared during the final planning stage in 1995. They need to be understood as gestures of tectonics to highlight some constructive elements, such as lintels. The skilful use of individual steel parts and entire steel structures at the Gr.-Orth. Church Allerheiligen in Munich can only be seen as influenced by Schattner, considered an architectural role model in the Catholic ranks of the 1980s.

The contemporary churches in Greece speak a completely different architectural language in their shape and materiality to that of the Greek-Orthodox church Allerheiligen in Munich. Newly built churches in Greece continue to be dominated by cross-dome constructions as has been common since the Byzantine era.[7]

With its white plastered facades, the Gr.-Orth. church Allerheiligen also evokes stereotypical images of a radiant "white" architecture, most common on the islands Cyclades and Sporades. Brannekämper deliberately chooses smooth white plaster because in his understanding this corresponds

to the pure image of a "Greek church" that Greece is known for on "every postcard".[8] In particular, the white churches on Santorini, which are based on simple geometries and have blue domes, are perceived around the world as being stereotypical of Greece's regional architecture, which is due, among other things, to years of targeted campaigns by the National Greek Tourism Organisation.[9] The dominant white colour in the architecture on the islands is mainly due to a decree by the dictator Ioannis Metaxas, according to which the houses in the Cyclades had to be painted uniformly white in order to contain the outbreak of cholera. Previously, the buildings were plastered in more natural colours as a visual protection against pirates.[10] The charming image of the Greek island architecture of the Cyclades and Sporades captivated architects at the CIAM Congress in 1933 thanks to photographs by Sigfried Giedion, which demonstrated his "appreciation of the unity between the built artefact and its natural environment"[11]. In his text "Le voyage en Grèce", first published in 1939 Le Corbusier also praised the Cycladic houses stating: "…[I] ignored the fact that the houses of the Cyclades, these bright white flowers, were still in bloom as proof, to our great consolation."[12] The contemporary image of the Cyclades is the complex product of historical development, tourism and the retrospective projections of architects and scholars.[13] In fact, the "white" architecture of the Cyclades represents only a small part of the diverse architecture of Greece from which most people of Greek descent in Munich can claim their origins. It is more remarkable that Brannekämper uses the "white" architecture of Greece in the design as a reference. Plastered facades like those in Gr.-Orth. Church Allerheiligen not only blend into Munich's cityscape but also align with the constrained budget of the construction project. Those of Greek roots who visit the Gr.-Orth. Church Allerheiligen regularly, feel reminded of their home country and consider the building to be a success, even if it speaks its own, usual architectural language.[14]

The design of the Gr.-Orth. Church Allerheiligen draws from both religious and local influences as well as broader trends of contemporary architectural language. The conversion project in the 1990s fell into the era of the so-called "second modernity", which "left behind the decorative narrative joy of a historicising postmodernism"[15]. The different stages of design for the façades between 1993 and 1995 can be seen as an example of fading post-modernism: with each new plan, Brannekämper approaches an architectural style of the early 2000s, which is characterised by even simpler forms. The Gr.-Orth. Church Allerheiligen was built prior to the Federal Chancellery in Berlin, designed by the architects Axel Schultes and Charlotte Frank. The competition in Berlin was announced in the same year that the church's foundation stone was laid in 1993 and was completed in 2001. The slender, high supports with narrowed capitals, wall slots and semi-circular motifs, as well as the white colour of the outer walls on both buildings, speak a similar architectural language. At the same time the design process of the Gr.-Orth. Church Allerheiligen is on the cusp of a new era, without crossing it: All plans continued to be drawn by hand by Brannekämper and his employees.

Nevertheless, some post-modern, historicising forms remain in the execution of the church. It is in the spirit of post-modernism to combine stylistic elements from different eras and cultures. However, the design in Munich is more "sober" and elegantly reserved to provide space and surface for the religious paintings that were added after the completion of the interior.

5. A NEW APPROACH FOR YOUNG MONUMENTS: PROACTIVE PRESERVATION

Buildings from the post-modernist period (1970s, 1980s, 1990s) are starting to be slowly considered as worth preserving. They are still relatively young and numerous, and so the core question becomes how the criteria will be set for buildings from this generation to be classified as monuments.

According to the Bavarian Monument Protection Act, monuments are classified as "of people created things or parts of them from the past, that are worth to be preserved because of their historical, artistic, urban planning, scientific or folklore significance in the interest of the general public"[16].

The Gr.-Orth. Church Allerheiligen is an outstanding example of a sacred building from the 1990s, that - in addition to artistic and design aspects - also offers a unique history in terms of ecumenical cooperation and social value for integrating a minority into a larger community. It is also a remarkable example for "renovating" an exciting church: while a restoration would not allow for adhering to the necessary liturgical requirements in the architecture, and an entirely new building would have been subject to new building rules, meaning that the footprint would be smaller.

At the same time, the church is relatively unknown to those who do not belong to this minority. Greeks from all over the city come to this church, especially on Sundays and religious holidays. On Sunday service, the church is visited by an average of around 300 people. While more and more people have been leaving the Catholic and Protestant church in Germany in recent years, Greeks abroad are increasingly turning to the church of their ancestors, "with which the life of their nation and their own are historically, spiritually and sentimentally linked."[17]

Finally, the Gr.-Orth. Church Allerheiligen in Munich illustrates how broad the scope for interpretation is for the term "renovation" in the 1990s. The project of the Gr.-Orth. Church on the footprint of the Catholic Church Allerseelen is essentially a new building in terms of its implementation and appearance. To what extent the term "renovation" might be justified in this context could be critically questioned because apart from the dismantled external walls, nothing from the previous building has been preserved. And yet, in a certain way, the previous building had a significant influence on the design process because the architect ultimately had to work within the constraints of the existing architectural "corset".

The Gr.-Orth. Church Allerheiligen therefore represents a radical transformation of an existing architectural structure, which serves the "pragmatic" purpose of bypassing building regulations rather than

exploiting the material value of the building structure or following the romanticism of continuing to use venerable walls.

Church conversions have been a common construction project for decades. However, it is uncommon for an existing place of worship to be converted to another denomination.

The architecture of (religious) minorities often struggles to be seen and gain recognition in mainstream society. The recently published book[18] on the history of this church, presenting exclusive archival material, is also an early wake-up call for local authorities to start considering its potential as a future monument before any renovation measures need to take place (Fig. 4). The more information publicly available about the history of a building, the more value and appreciation it can attract. ■

BIOGRAPHY

Korinna Zinovia Weber studied architecture at TU Munich and ENSA-Paris-La-Villette. She received the Theodor-Fischer-Preis from the Zentralinstitut für Kunstgeschichte in 2022. Until 2023, she was lecturer, project manager and research assistant at ETH Zurich, at the chairs of Prof. Markus Peter and Prof. Tom Avermaete. Until 2024, she worked as a scientific collaborator at EPF Lausanne. Her book on the history of the Greek-Orthodox Church in Munich, financially supported by the Geschwister- Boehringer Ingelheim Stiftung, was released in fall 2023 at Kunstverlag Josef Fink. She has been a member of Docomomo Switzerland since 2019.

PINACOTECA CONTEMPORÂNEA

CARLOS ALBERTO MACIEL
UNIVERSIDADE FEDERAL DE MINAS GERAIS

PAULA ZASNICOFF
IBMEC – BELO HORIZONTE

ABSTRACT

This article aims to present Pinacoteca Contemporânea, an intervention in pre-existing structures whose scale and architectural characteristics may be understood as ordinary, especially when compared to its neighbour, the monumental building of Pinacoteca de São Paulo, designed by architects Ramos de Azevedo[1] and Domiziano Rossi in 1896.

Pinacoteca Contemporânea is the third unit of the Pinacoteca do Estado de São Paulo, the largest Brazilian museum, located in the city of São Paulo. It is an intervention in buildings remaining from two public schools, the first - Escola Modelo da Luz -, also designed by Ramos de Azevedo, was partially demolished after a fire in the 1930s, and the second - Escola Pública Prudente de Moraes, designed by Helio Duarte[2] – is a modern building erected in the 1950s and in use until 2015. The school was part of a public programme called Convênio Escolar (the School Covenant), and was in a state of near abandonment, with accelerated obsolescence when a public call was made for conceptual proposals for converting that structure into a new museum unit. Some of the main issues that required addressing included the urban degradation in the surrounding area, the potential of integration with the public park where it is located - Parque da Luz – the first public garden in the city, and the need to redefine the opening and accessibility of the building, as well as to expand areas for exhibitions, events, and collections[3].

1. INTRODUCTION: DESIGN PRINCIPLES

The project for Pina Contemporânea[4], carried out between 2018 and 2021, and constructed in 2022, is based on the following principles:

- an acknowledgement of place, recognising the urban scale of the pre-existing structures, which informed the overall integration of the new museum with Parque da Luz, its vehicular and pedestrian accesses, as well as its relationship with the original building of Pinacoteca, the Casa do Administrador do Parque (park administrator's house), and the various surrounding areas of listed properties in the urban ensemble;
- a creation of a public urban connection space, constructing a large open and public space for urban connection and articulation between the various volumes that constitute the ensemble;
- an acknowledgement of architectural scale - recognising the historical remains and their distinct periods, from the construction of Escola Modelo da Luz by Ramos de Azevedo, which was burned down in the 1930s, to the modernist building constructed in 1950 in the context of Convênio Escola - by dedicating activities compatible with their original structure and spatiality. This spatial organisation also guided the definition of the entire new intervention to constitute a unified cohesion with;
- design of flexible spaces to expand the possibilities of exhibitions and uses (both indoor and outdoor areas);
- physical and visual integration with open spaces, emphasising the public character of the institution and its openness to the immediate context through physical and visual integration with open spaces. This includes the qualification of the designed, sheltered, and open spaces for appropriation, both in Institution-programmed events and in free situations, to shape the ensemble as an extension of the public space of the park;
- adoption of sustainable solutions, using, for example, industrialised construction for the roof and circulation ring, with a structure made of glued laminated wood and steel to minimise the impact of implementation on both existing buildings and Parque da Luz. In addition, various engineering strategies will be employed to reduce energy and water consumption according to LEED recommendations.

2. RECOGNISING THE PLACE

Recognising an axis of urban articulation, and introducing a route that crosses the terrain connecting the park to the street, is the main foundation that guided the design of the ensemble. This square, dedicated to pedestrians, is positioned along the axis defined by the Pinacoteca building, whose intervention, carried out in the 1990s by architect Paulo Mendes da Rocha, reversed the internal articulation of the original neoclassical building. The interpretation, on an urban scale, of that architectural axis of the neighbouring building is the main organiser of the flows of access to the new spaces of Pinacoteca Contemporânea.

1. Francisco de Paula Ramos de Azevedo (1851-1928) was a Brazilian architect and professor who designed several public buildings in São Paulo.

2. Hélio de Queiroz Duarte (1906-1989) was a Brazilian architect, urban planner and full professor at FAUUSP - Faculdade de Arquitetura e Urbanismo da Universidade de São Paulo. As a specialist in school architecture, he coordinated the Convênio Escolar.

3. Comprehensive documentation regarding the intervention project can be accessed at https://arquitetosassociados.arq.br/pina-contemporanea/

4. Designed by Arquitetos Associados - Alexandre Brasil Garcia, André Luiz Prado, Bruno Santa Cecília, Carlos Alberto Maciel e Paula Zasnicoff - with the participation of Silvio Oksman.

It reconstitutes, on a different scale and with a more refined ambience, with landscaping that is a continuation of the park. The idea of the schoolyard was originally defined by the parallel implantation of two distinct built elements that can be recognised as ordinary architectures of small scale and different times.

The need to respect the scale and low height of the remaining buildings guided the creation of a basement level for the exhibition area and technical areas. The listed building regains its presence from an urban point of view through the removal of walls and the opening of gardens to the avenue.

3. RECOGNISING THE MODERNIST BUILDING

Recognising the structure and spatiality of the main building of Escola Pública Prudente de Moraes, which was designed by Hélio Duarte[5], played a role in guiding project and restoration decisions. The original building, organised in two longitudinal bodies articulated by a central hall, and features two different modular orders of the reinforced concrete structure, both of small-scale and small-span openings.

The first, in regards to the one-story southern block, had a central circulation that provided access to the school's administrative and support spaces. This block was mostly dedicated to the activities of the Library and Documentation Centre. The independent structure allowed for integrating the main spaces into two naves, concentrating all support spaces in the central span of the former circulation without conflicts between the new uses and the structure. This approach frees up the facades, opening the spaces for the public and workstations to the inner square to minimise the negative impact of noise and environmental pollution from Avenida Tiradentes while, at the same time, activating the connection with the main public area, the covered square. Located facing the front garden of Avenida Tiradentes, the collections are more isolated from public spaces, with strict temperature and humidity control.

The second structural order of the building, of the two-story northern block, which is entirely dedicated to the technical reserve of the artistic collection, presents vertical circulation adjacent to the central body and horizontal circulation facing the inner square. The rigorous structural pattern corresponding to the layout of the classrooms, with two structural modules and two windows per room, is also present.

In this block, the central classroom's floor slab was removed to create a double-height internal space to display large-scale collection items. Additionally, the walls dividing the classrooms were removed, taking advantage of the independence of the reinforced concrete structure to allow for greater flexibility in the management of the collection. The original flooring patterns were preserved, clearly marking the original compartmentalisation and the location of the removed partitions. The larger and heavier collections were placed on the ground floor, while smaller and lighter objects were located on the second floor to match the load capacity of the original structure.

The central block serves as the main welcoming and information space of the new museum. It defines an axis of architectural articulation, that resonates in the new roof, the mezzanine, the Grande Galeria (larger exhibition space

5. The first publication of the modernist project was made in the Habitat magazine, under the editorial guidance of the duo Lina Bo and Pietro Maria Bardi, in 1951. This issue brought an extensive dossier on the activities and projects of the Convênio Escolar ongoing in São Paulo. Two texts published in this edition, signed by Lina Bo Bardi and Hélio Duarte, argued strongly for the need for modern architecture to be adapted to urban school buildings in the contemporary society of that time. The original design of the Convênio Escolar for the Prudente Moraes School was not fully executed, encompassing plans for the demolition of the remnants of the Escola Modelo da Luz.

at the basement), and provides access to the Pavilion on the west side of the site. The internal organisation and materiality of the entrance hall - a space that contributes to defining the identity of the original building by associating the filtered light of the latticed element of the front facade and the curved wall that defines the viewing plane and axis of symmetry of the main entrance - were fully preserved, and a reception counter introduced (**Fig. 1**).

4. RECOGNISING THE REMNANTS OF THE ESCOLA MODELO DA LUZ

The buildings on the west facade that define the front of the park were restored based on the recognition of their primary constituent elements, assigning them uses compatible with their spatiality focused on their potential for activating the square. They now house an exhibition gallery, studios, a shop, restrooms, and administrative space.

In the eclectic annexe, a remnant of the first school - Escola Modelo da Luz -, a lower addition along Rua Ribeiro de Almeida was demolished. Its dissonant design detracted from the symmetrical order of the building, which was characterised by the prominent main door, emphasised by the original design of its roof. The demolition of this side section improved the visual integration of this remnant with another existing building outside the intervention area, the Casa do Administrador do Parque, a listed building of a similar scale, typology, and construction pattern. Its use as administration is consistent with this understanding of the ensemble. Its internal layout creates a distinctive room, reinforcing the reading of the ample space with generous ceiling height, defined by the clear geometry of its roof, which has been fully restored with a new wooden structure and French-style roof tiles. The original fenestrations were restored, whenever possible, based on traces present in the remaining walls. The colours of both the masonry and the joinery followed those identified in the oldest layers among those indicated in the survey.

The second element of this preserved ensemble is the pavilion defined by the sequence of steel portal frames, whose geometry and materiality were identified and mapped in the surveys conducted in compliance with the guidelines of the municipal preservation agency (DPH). Due to the absence of records of its original conformation, the project is based on the existing rhythm of the portals and the appreciation of this exceptional element - a steel structure from the early years of the 20th Century - to define the ambience of the ensemble of spaces. The existing compartments and construction elements that walled and concealed the metal elements were removed in their entirety to make room for a pavilion with greater internal visual permeability and greater integration with the immediate surroundings, both on the side facing the new square and on the sides facing Parque da Luz, in order to redefine the undesirable back appearance that this building presented at the interface with the Park. A specific aspect of the portal geometry defines the entire intervention: the height of 2.50 metres is determined by the differentiation between the generic concrete pilasters from which the steel structure develops. A new envelope is constructed independently of the delicate structure to

accomplish this. This is achieved through two operations: the raising of a wall to a height of 2.50 metres, using the same material as the square floor and extending the material of the metal roof above that height.

This differentiation avoids the need for a third material for the facades, accentuating the horizontal and elongated character of the pavilion, which contributes to defining the fronts to the square and the park. This strategy seeks to minimise the abundance of forms, volumes, and materials to preserve the hierarchy and importance of the pre-existing delicate and small-scale elements. In this pavilion, the two smaller ends are fully open. On one side, the exhibition hall located on the south face - Galeria Praça - provides a view of Parque da Luz with the Pinacoteca brick building as a backdrop. On the other side, it opens the staff living area to a private courtyard that separates the small annexe of the Escola Modelo da Luz, intended for administration, from this pavilion. This separation is intentionally designed to restore the unity of each section, each with its own ordering principles. At the same time, it maintains a subtle continuity between both by extending the lower wall of the pavilion to the annexe, ensuring the continuity and linearity of the square boundary **(Fig. 2)**.

5. INTEGRATING THE ENSEMBLE: BASEMENT, SQUARE, MEZZANINE, AND NEW ROOF

Promoting the integration of such distinctive buildings constituted the main challenge of the project. Therefore, the emphasis is on designing the void: a generous square at ground level, which is shaped by the overlap of three levels of use: first, the Grande Galeria located in the basement, whose underground location avoids the creation of a new dissonant volume that could compromise the ordinary scale of the pre-existing elements; second, the public square at street level; and third, the mezzanine, on the upper level, six metres higher, overlooking the front garden and to the park, partially overlapping the south block of the modern building at a level that fully preserves all its enclosing walls, with the minimal possible impact, and at the same time, offering a new experience of integrated vision, previously unavailable, which restores the visitor's understanding of the ensemble. This overlap is crowned by the new illuminated roof, a fundamental element in constructing the new unit of the ensemble.

In addition to the exhibition, the basement houses technical, support, and service spaces under part of the pavilion. During its construction, care was taken to avoid approaching both the modern building and the foundations of the eclectic annexe. The process involved the removal of the steel portal frames, which were restored outside the construction site and reassembled. Such an approach was taken because it aligns with the tectonic logic based on the assembly of lightweight elements, making it the simplest and most effective solution for their restoration. The new underground infrastructures reduce the impact of building infrastructures on this delicate pavilion, ensuring that the remaining metal elements stand out.

The mezzanine is designed as an independent steel structure, which interfaces with the south wing of the modern building. It provides support

and access points for the light structure on the central pillars of the existing building, allowing for structural reinforcements to be made without compromising the integrity of the facades and main architectural elements that characterise the modern building. The lightweight metal structure minimises assembly time and impact on those pre-existing ordinary constructions.

For the vertical articulation of this set of public spaces, four elements were constructed: the bleacher staircase next to the central walkway, which, like a redesign of the floor, provides access to the lower level of the exhibition area within the square; two metal staircases provide access to the mezzanine, offering views of the square and Pina Luz; and the main element for vertical articulation that provides universal accessibility: a panoramic pair of elevators that offers, in the central void of the square, providing an analogous - now open, and urban-scale - experience similar to that of the elevator designed by architect Paulo Mendes da Rocha in the third courtyard of Pina Luz.

Finally, the design features an illuminated ceiling made from high environmental performance and low impact material - glued laminated timber – on the one hand is inspired by the illuminated ceiling designed by Mendes da Rocha for Pinacoteca Luz while, on the other hand, incorporates the heterogeneity of shade through variation in the spacing and profile of the beams, echoing both the experience of visiting the internal space of Pina Luz and the experience of walking under the forest canopy of Jardim da Luz. By presenting itself as a new roof in the open space, it reverses the introspection of the glazed ceiling of Pina Luz, visible only from its interior spaces, and shapes a new element in the urban landscape. Its discreet presence is ensured by its position set back from the main facade of the modern building, which maintains its hierarchical dominance in the ensemble seen from Avenida Tiradentes. Seen from the other side, from the Park and within the square, it signals the emergence of a new public space. Said space is characterised by programmatic indeterminacy, sustainability, and high urban potential in an effort to create a "significant unnamed space"[6], as professor Flavio Motta once defined some spaces in Brazilian modern architecture. These spaces do not have a pre-determined function but present a generosity in terms of scale and urban integration, allowing them to form important urban fragments along with architectural artefacts.

6. THE IMPORTANCE OF RENOVATION

It is worth highlighting that the Pinacoteca Contemporânea, although situated within a designated heritage context, differs significantly in material quality and the integrity of its pre-existing structures when compared to the original Pinacoteca building, designed by Ramos de Azevedo and later intervened by Mendes da Rocha, which holds high historical and architectural value. On the other hand, the remnants of the original school hold substantial historical value but lesser architectural importance. This discrepancy justifies the fact that its heritage designation focuses on its volumetric preservation. The materials used are quite ordinary, and given that the original design was only partially implemented and, at the time of intervention, it presented numerous remnants

1

3

2

from other periods, coupled with several low-quality buildings improvised to meet immediate functional demands, the overall structure allowed for a higher degree of intervention. This opportunity is evidenced by the addition of a large underground floor, the full opening to the immediate context, and the articulation of the remaining elements through the illuminated ceiling defining the Central Square. Consequently, the more extensive intervention seeks to balance different levels of preservation according to the distinct parts, allowing substantial modifications to better enhance its public use and its ability to articulate and contribute to the renewal of the immediate context, including the city and the park. It is not difficult to imagine that this would be quite unlikely in a complex of high architectural value protected by the most stringent integral preservation regulations, which would likely hinder or prevent a comprehensive redefinition of the complex as undertaken **(Fig. 3)**. ■

BIOGRAPHY

Carlos Alberto Maciel is a Brazilian architect and urban planner who graduated from the Federal University of Minas Gerais (UFMG) in 1997. He obtained his master's degree in 2000 and a Ph.D. in Theory and Practice of Design in 2015, both from UFMG, where he currently serves as a full professor of Architectural Design. His research interests encompass architectural production beyond mere function and language, focusing on mapping design strategies associated with mutability, growth, and industrialisation, in the aim of fostering more virtuous relationships with the urban environment.

Paula Zasnicoff is a Brazilian architect and urban planner who graduated from the School of Architecture and Urbanism at the University of São Paulo (FAUUSP) in 2000. She earned her master's degree from UFMG in 2007. Currently, she serves as a professor at IBMEC in Belo Horizonte. Her theoretical research centres on museum architectures and public spaces, themes that also inform her professional practice.

WEST BUND SHANGHAI: THINK TANK FOR ART

JACOPO BENEDETTI
TONGJI UNIVERSITY, CHINA

CARLOS EDUARDO COMAS
FEDERAL UNIVERSITY RIO GRANDE DO SUL, BRAZIL

ABSTRACT

The Tank Art Center is one of the centrepieces of the West Bund, an art- and landscape-driven urban renewal project along the southwestern banks of the Huangpu River in Shanghai. The area bears evidence of the city's productive past, including large-scale loading cranes, warehouses, wharves, runways, and technical facilities. In the redevelopment, former industrial and infrastructural sites have turned into design opportunities for international firms and Chinese independent architects called to work on new cultural containers along the river, either by public clients or private entrepreneurs.

Beijing-based OPEN Architecture (founders and principals Li Hu and Huang Wenjing) was tasked with the design of the Tank Art Center in 2013. Construction took place between 2017 and 2019. The program of the Center unfolds in and around a cluster of five decommissioned aviation fuel tanks built in the 1980s to serve Shanghai's former Longhua Airport—China's first major aviation hub and once the largest international airport in the Far East. Of all new cultural venues along the West Bund, the Tank Art Center most closely interweaves the two urban themes of the redevelopment project: building and landscape, park and museum. More critically, in OPEN's design, the preexisting infrastructural heritage is turned into a substantive element of the contemporary layout, neither hindering the new nor being subordinate to it.

This paper begins by framing the Tank Art Center within the recent transformations of Shanghai's riverfronts. Site visits, web research, and access to the architects' archive allow close reading of the grounds before and after renovation. OPEN's approach to the adaptive reuse of the fuel tanks is thoroughly described and analysed, offering critical and comparative insights on the design.

1. WEST BUND

Only 3 out of the 150 km of Shanghai's riverfronts were open to the public until 1990, the banks of the Huangpu River and its tributaries being primarily used for trade and heavy industry. Ensuing efforts to make these banks publicly accessible meant providing a dense and overpopulated urban core with a network of open spaces, while freeing up long stretches of waterfront property. By demolishing or repurposing industrial sites along the Huangpu, renewal reflected the municipal government's ambition to transition Shanghai from a city of production to a city of consumption.

One of the most successful instances of riverfront rehabilitation is the West Bund, a 9.4 square kilometres former brownfield site in the Xuhui district, nestled to the south of the old city, between Shanghai's middle and outer ring highways. Although this area represents only 5% of the city's renewed watersides, it is the only one that has established itself as an urban destination, effectively drawing citizens and tourists away from the central districts of Shanghai.

The West Bund area has a long history. In pre-industrial times, it was covered by gardens and orchards, dominated by the pagoda of the Longhua Temple and Monastery (built 242 CE, then destroyed, reconstructed, and restored multiple times until 1954). The area housed a Kuomintang prison in the interwar period, memorialised by the Longhua Martyrs' Hall (1995). During Japanese occupation (1937-45), it served as detention camp for foreign residents. Most notably, the Xuhui riverfront was the seat of two crucial modern transport infrastructures, now dismissed: the Nanpu Railway Station, used both for cargo and passenger transport, and the Longhua Airport, one of the cradles of Chinese aviation. Longhua occupied most of the Xuhui riverbanks. Established as a military airfield (1922), with both land and water runways, it evolved into a passenger hub (c.1930). By the mid-1960s, air traffic had largely shifted to Hongqiao. Longhua gradually declined and finally closed (2008). The city fabric had enveloped the once remote airport.

Renovation in the area started in 2013, the first buildings and open spaces completed as early as 2014. Both urban renewal and urban rebranding, the West Bund program was to rival international landmark districts such as London's South Bank, Paris's Rive Gauche, and New York's Museum Mile. Aiming to conjure the appeal of a deterritorialized international hotspot, its very name was inspired by these precedents. The program's economic drivers are multifaceted. Nonetheless, it is broadly a culture-led urban redevelopment that is not aimed at promoting the specific cultural heritage of Shanghai or the Xuhui district, but rather at fostering an abstract and polished idea of culture that aligns with global models in the arts, media, fashion, and design industries.

At the core of the program is the so-called "Cultural Corridor": a tight sequence of public and private art museums, ateliers, and galleries adjacent to the riverfront, enjoying tax incentives and rent-free leases. The Corridor—marketed as the largest outdoor art-exhibition area in the world—caters to the aspirations of the growing high-income transnational

middle class of the Chinese metropolis while simultaneously leveraging the burgeoning growth of its art ecosystem.

Since the 2010s, Shanghai has progressively become an international centre for the display, storage, and commerce of ancient and contemporary art. As of October 2021, Shanghai had 96 active museums—25 state-owned and 71 private—and hosted an average of 2,000 exhibitions per year. The number of art galleries increased from only 47 in 2001 to 770 in 2019; in 2021, the West Bund alone featured as many as 110 galleries.

How does this broader program relate to the adaptive reuse of industrial and infrastructural heritage? The riverbanks of the West Bund bear substantial evidence of the area's productive past, including large-scale loading cranes, warehouses, wharves, runways, and technical facilities. International firms and Chinese independent architects were involved in designing new cultural institutions on the former industrial or infrastructural sites, commissioned either by public institutions or by Chinese entrepreneurs and collectors such as Liu Yiqian and Wang Wei (Long Museum), Budi Tek (Yuz Museum), He Juxing (START Museum), or Qiao Zhibing (Tank Shanghai). The architects have each dealt differently with the context and material traces of the site's past. Within a span of a few kilometres, one can witness a wide range of approaches, from the formal re-evocation of demolished buildings—Jean Nouvel's START Museum mirroring the position, plan, and silhouette of the former Nanpu Railway Station—to the staged isolation of historical fragments—the Beipiao Wharf in Atelier Deshaus's Long Museum—, or the assimilation of old disjointed parts within new architectural ensembles—the Longhua aeroplane hangar and the glass façade in Sou Fujimoto's Yuz Museum.

The Tank Art Center (Tank Shanghai for short, 2013-19) by OPEN Architecture (founders and principals Li Hu and Huang Wenjing) stands out. Of all new designs along the riverfront promenade, it most closely interweaves the two main urban themes of the West Bund: park and museum. More critically, here the preexisting infrastructural heritage is effectively turned into a substantive element of the contemporary layout, neither hindering the new, nor being subordinate to it[1].

2. ART TANK

Tank Shanghai occupies a 4,75 ha L-shaped lot on Longteng Avenue. Made up by a big and a very small trapezoid, the site is two metres lower than the avenue. The brief foresaw both new building and the reuse of five ordinary cylindrical aviation fuel tanks within the lot **(Fig. 1)** but was otherwise fluid until Qiao Zhibing became boss (2017).

The site extends between the riverfront to the east and Longteng Avenue to the west, the Longhua Helicopter Airport (renovated 2016-19) to the north and the Longyao Road Tunnel (completed 2010) to the south. The five 15-metre-high tanks date from the 1980s and form three rows. The row comprising tanks 1 (in the small trapezoid) and 2 (in the big trapezoid) fronts Longteng Avenue. The row comprising tanks 2, 3 and 4 is roughly

1. We thank OPEN Architecture for providing us with firsthand information and images on the project.

perpendicular to the first. The diameter of tanks 1, 2, and 3 is 24 metres, that of tanks 4 and 5 is 28 metres. The third row comprising the wider tanks forms an obtuse angle with the second. The east-west axis of tank 5 bisects the big trapezoid lengthwise in roughly equal areas; its north-south axis crosses the site halfway. At the site's southernmost vertex, the ventilation tower for the tunnel serves as a signpost, framing the big trapezoid together with tank 2. A big dome, once a cement factory, rises in the neighbouring site south of the tunnel **(Fig. 2)**.

OPEN's straightforward scheme merges cultural venue and urban park. For architects Li and Huang, an art centre need not be temple, palace, factory, or depot, but develop below and beside greenery, recalling caves and/or garden pavilions. The Geffen Contemporary at MOCA in Los Angeles by Frank Gehry (1979-83), a former warehouse, is less of a precedent than the Louisiana Museum of Modern Art near Copenhagen by Jørgen Bo and Wilhelm Wohler (1955-58/66/76/82/91) and the Oakland Museum of California by Kevin Roche, John Dinkeloo, and landscape architect Dan Kiley (1962-69). Nevertheless, the Shanghai site leads to a diverse use of greenery, paving, and architecture both to characterise border conditions and to create geometrical order within the site's irregular perimeter.

With direct public access, tanks 1 and 2 form a duo although assigned to live music and a restaurant, respectively. On the northern border, a side street runs along the heliport's fence to provides parking space and service access to tanks 3 and 4, the main exhibition galleries. Tanks 1, 3, and 4 appear in full height from the street, relating in scale to the heliport buildings. In contrast to this hard edge, a forested expanse bordered and crisscrossed by pedestrian pathways covers the tunnel and blurs the limit between Tank Shanghai and the neighbouring site. Given the transverse disposition of tanks 4 and 5 as well as their peripheral and central location, respectively, plus the distinct qualities of riverfront and city front, the design highlights two elements in a Yin-Yang relationship: a 55-metre paved square and a 45-metre-long freestanding gallery for special exhibits between an internal green and a riverside forecourt. Typological progression, complementation and polarity apply.

The square—the architects call it "urban plaza"—is defined primarily by two elements. One is a Z-shaped garden surface adjoining the tanks and the forested expanse. The other is a complex of landings, stairs, and cascading pools—the architects call it a "stepped waterscape"—that develops between the outer row of tanks and a diagonal ramp starting next to the tunnel tower and ending at the square's southwestern vertex. The Z-shaped garden is partly planted on ground, partly on a one-story-high roof slab **(Fig. 3)**. Below it, the exhibition wing runs east-west, while the entrance wing runs north-south. Window walls giving onto the square enclose both wings. A multipurpose space, tank 5 is extended by a long stage flush with the square's edge and a short one towards the green, both reinforcing axiality.

Tank Shanghai is a cut-and-fill operation: visitors go up to enter tanks 1, 2, and the rooftop garden planted with waist-high vegetation **(Fig. 4)**; down the stepped waterscape to access the square and the art centre, either by circuitous

stairs or directly via the ramp at one end and narrow steps at the other. To increase the interest of static forms for moving bodies, the southern border of the cascading pools is on axis with the projecting stages and a large circle on the square defined by misting devices; besides create a cooling, foggy microclimate in summer, the devices recall a demolished sixth tank. Fronting both the circle and tank 3, a boxy outbuilding with a niche-like platform open to the square replaces part of the forested expanse's outer pathway, reinforcing spatial enclosure while allowing for access to the freestanding gallery—the architects call it "Project Space"—and its surroundings.

The striated metallic eastern facade of the Project Space is the blank backdrop to a green comprising level and sloping lawns, separate seating areas for performance at the river stage. The green—the architects call it "event plaza"—is defined by tank 5, the Project Space, and two additional elements. The level lawn's northern side turns into a grassed over hip roof rising from the ground, a camouflaged service facility like its counterpart to the south amidst the forest, the "Reflecting Gallery" clad in shiny metal on an irregular hexagonal plan. The green is geometrically less strict than the square. The level lawn's eastern side diverges from the entrance wing, for the Project Space rectangular plan parallels an existing pool fronting the river. Once used by Longhua Airport firefighters, the pool is now inscribed into a rectangular lawn partly occupied with an olive grove **(Fig. 5)**.

Like the tanks, the Project Space has two faces. Re-proportioned by the new construction, the tanks crown the rooftop garden, evoking both elementary church domes and flat-topped hills, ready-mades gracing a man-made landscape. From the internal street, their utilitarian lineage shows. From the green, the serrated roof profile of the Project Space cries "factory," each triangle corresponding to one band of skylights. From the river, the industrial allusion gives way to a long, elegant portico supporting a monopitch roof that slopes inwards; the green—and watery—forecourt adds to the Project Space presence. Scale manipulation helps to highlight the transformation of elements associated with pragmatic infrastructure into semantically loaded superstructure, from the realm of need to that of desire. New portholes in the tanks allude to ships anchored nearby while reviving Purist architecture's infatuation with movement in the 1920s.

Visitors can go directly to the riverfront by the rooftop garden or by the forested expanse pathways. But going inside is rewarding. Each tank interior is renovated with a different functional and formal perspective, variations on how to decompose a drum, how to combine archetypal circularity with linearity. Radial spaces are accessed in the art centre by itinerant spaces of Neo-Purist allure, parading the free plan behind the window walls. Curvilinear ramps and staircases act as expanded and sometimes conical bases for the tanks, respecting their structural limitations. Conflating need for lighting and structural autonomy of the tanks, roof slabs are separated from the tanks by glazed bands. Walls and ceilings are white, cement floors are grey, cylindrical columns expose their concrete mostly upright (the 1920s way) but at times inclining (the 1950s proposal).

OPEN manages well the balancing of elite art and popular leisure at the same time it integrates existing ordinary elements into a new composition of far higher aesthetic status. In this sense, Gehry's MOCA is definitely a precedent, maybe not as close as Lina Bo Bardi's SESC Pompeia Leisure and Culture Center in São Paulo (1976-86), in which the adaptive reuse of a drum factory as a multipurpose covered plaza with library and exhibition spaces is associated to the creation of significant recreational space, both enclosed and open. Concrete grain silos, so dear to Le Corbusier and Walter Gropius, have been recycled as housing, and the brick-clad Vienna Gasometers too. Yet, the contemporariness of the Shanghai tanks (1980) and the relative newness of steel oil storage tanks in general (they appeared in the market around 1900-20) are remarkable, not to mention the fact, that like silos and gasometers, they were not supposed to become human activity containers.

Tank Shanghai makes one reflect about current disciplinary culture and recognize how much it still relies on the academic design tradition. OPEN uses a-stylistic techniques to create order within the irregular site. The obligatory reference is the succession of axially symmetrical pieces (façade, entrance, and *cour d'honneur*) in Antoine Le Pautre's Hôtel de Beauvais (1657), to which OPEN replies with the entrance wing's axially symmetrical elevation, the presence of Tank 5 strong enough to compensate for the near-symmetry or incomplete regularity of the plaza. Shifting axes of movement, as prompted by the Project Space, points to another academic staple, Auguste Choisy's analysis of the Parthenon (1865).

Nevertheless, if the techniques can be said a-stylistic, the result is not. Tank Shanghai is eclectic and historicist in a subtle way, as it prefers formal integration to contrast. It is a subdued temporal patchwork. Most of it revives modern architecture of the 1920s (and a bit of the 1950s) to go with tanks of the 1980s, which many deem timeless given their elementary geometry, but realistically date to the 1900s. Incidentally, the first Venice Architecture Biennial happened in 1980 to celebrate the postmodern past. Stubbornly, modern architecture as a formal system refused to die, having shed its International Style uniform even before its postwar hegemony. It became historicized as pluralist, and survived, historicist or eclectic in a contemporary way, and kept expanding, as OPEN intimates by bringing to the party the folds of the 1990s.

Typological recall enriches the temporal patchwork by giving a cross-national dimension to the marriage of forms transient and long-lasting, if not timeless. One may link the urban plaza to Michelangelo's three-sided Campidoglio (1534-1653) and its palaces renovated as museums, and the green one to Anglo suburbia. But it is equally valid to see them as the updating of the traditional Chinese courtyard, singular or successive, palatial and domestic, the tanks playing big roofs, love of the garden always alive. Relations can be established with the classic villas where drums and boxes interact, from Andrea Palladio's Villa Rotonda (1567-90) to Le Corbusier's Savoye (1926-31). But drums and boxes also interact in Beijing's Temple of Heaven (1406-20) turned into a park (1918) and tourist draw. Whether the word is contemporariness or modernity, the subject is change within continuity.

Refreshingly, OPEN does its job without extravagant forms of easy iconicity, endorsing maybe President Xi Jinping's indictment of "weird" architecture (2014). The limitless, tragic sublimity of a derelict site is replaced by a controlled mix of pastoralism and stateliness that provides understated, refined delight, and it would be preposterous to assert that only the "transnational capitalist class" can appreciate understatement and refinement. Chameleon-like it is because of its simplicity, institutionally consolidated Tank Shanghai is now also a venue for fashion events and corporate gatherings, a scenic setting for wedding photography, a destination for both picnickers and art-goers. In global travel parlance, worth a detour. ■

BIOGRAPHY

Jacopo Benedetti is an architect and Postdoctoral Fellow at the CAUP of Tongji University in Shanghai. He is founding partner of the award-winning architectural office Spazi Consonanti based in Rome, Italy. He studied architecture at the RWTH in Aachen, Germany and at the University of Rome, "La Sapienza". He received his PhD in architecture from the University of Roma Tre. In 2021 he has been Visiting Fellow and Visiting Lecturer at the TUM in Munich, Germany. He has lectured and published on the topics of heritage, architectural design and interdisciplinary approaches to the interpretation of the built environment.

Carlos Eduardo Comas studied architecture in Porto Alegre (Universidade Federal do Rio Grande do Sul), Philadelphia (University of Pennsylvania) and Paris (Université de Paris- VIII). He is Professor Emeritus at his alma mater, a member of the permanent faculty of its Graduate Program in Architecture as well as the advisory boards to IPHAN (Brazilian National Heritage), ANPARQ (Society of Brazilian Graduate Programs in Architecture), and DOCOMOMO Brazil. Besides keeping a small professional practice, he has written, lectured, and curated exhibitions about Modern Architecture and Urbanism, in his native country and abroad, editing and contributing to several books, catalogues, and journals.

CORPORATE ARCHITECTURE IN BRUSSELS: FROM OBSOLESCENCE TO HERITAGISATION. LA ROYALE BELGE AS CASE-STUDY

JEAN-MARC BASYN
FACULTY OF ARCHITECTURE ULB LA CAMBRE HORTA,
URBAN.BRUSSELS, DOCOMOMO.BE

ABSTRACT

Brussels is host to many national and international institutional and private corporate office buildings. The construction of office buildings on a massive scale in the second half of the 20th century was the most striking feature of Brussels' urban structure. This period also saw major infrastructure works and the development of the green periphery, with the emergence of new monofunctional office districts.

This typology is particularly fragile due to its rapid obsolescence and confronted with poor sustainability and strong economic constraints, too often reduced as an object of consumption lacking in image. In recent times, some examples of Corporate architecture have become protected as heritage sites, while many others are being repurposed for new uses, often without much respect for their heritage values. This paper intends to present a brief overview of the heritagisation and urban policy related to office buildings in Brussels (IBM, WTC, ING, Generali,…), with a focus on the more recent significant intervention on La Royale Belge.

La Royale Belge (1967-1970) insurance company is an emblematic office building in Brussels' green periphery. Thanks to its audacious architecture, its integration into the landscape and the quality of its interior design, La Royale Belge is certainly an icon of international Corporate architecture. When the building faced a possible demolition, it was officially listed in 2019. The building then underwent a substantial and delicate renovation-restoration-transformation in a successful multifunctional programme.

1. INTRODUCTION

Brussels is host to many international and national institutional and private corporate office buildings. With its 1.24 million inhabitants, around 1.700 office buildings and some 12.5 million m² of office space[1], Brussels has remained at the heart of office architecture since the second half of the 20th century.

This typology is particularly fragile due to its rapid obsolescence and confronted with poor sustainability and strong economic constraints, too often reduced to an object of consumption lacking in image.

In the years following World War II, Brussels took a resolutely functionalist turn, and the construction of office buildings contributed significantly to this irreversible urban transformation. The context was one of unlimited growth, unbridled mobility and tertiary development: The establishment of international institutions, numerous national and international company headquarters, the proliferation of Belgian administrative bodies and preparations for Expo 58 had a drastic impact on the morphology of Brussels, with new axes and completely redesigned districts.

Today, the refurbishment of office buildings is a topical issue that involves heritage value, sustainability, contemporary urban policy issues (densification, diversification, mobility) and economic requirements (real estate, relation private-public, usages).[2]

Recent debates on the extension of the notion of heritage to recent architectural production in general and to the office building typology in particular are undoubtedly contributing to the heritagisation and valorisation of these symbols of consumer society through their contextualisation.[3]

In Brussels, there is a favourable regional policy towards recognising recent heritage recognition; with the need to abandon the single-purpose constraints of most office buildings in favour of multifunctional solutions that better respond to new societal needs. Such a shift is influenced by changing working habits due to the COVID 19 Pandemic and the need for less office space. Real estate players are learning to leverage the 'design' or 'vintage' potential of an office building, contributing to various emerging approaches in this ongoing development.

2. OFFICE BUILDINGS AND MODERN URBAN PLANNING

The construction of office buildings on a massive scale in the second half of the 20th century was the most striking feature of Brussels' urban structure, accompanying major infrastructure works and the development of the green periphery.

2.1. THE BRUSSELS NORTH-SOUTH RAILWAY JUNCTION

In Brussels, the development of the tertiary sector was initially linked to the major infrastructure works of the North-South railway junction. These titanic works, which cut through the medieval urban fabric, began in 1911 and were interrupted by the First and Second World Wars. They were finally completed and inaugurated in 1952[4]. It has redesigned part of the historic centre, creating

4. Start of the works in 1911 till 1914 and the beginning of World War I. Works restart in 1936 and continue partially during the World War II. Inaugurated by King Baudouin in 1952. 3,1 km long : 200 m viaduct + 2.000 m tunnel + 900 m viaduct ; 6 train tracks ; 5 new train stations : North, Congress, Central, Chapel, South ; around 1.500 trains per day.

new axes and new building blocks, in short, a new urban morphology in which the service sector will dominate. A comprehensive collection of office architecture from the 1930s to the present day is being developed along these new axes. One of the most illustrative examples is the so-called Ravenstein block, which encompasses the Shell building (Alexis Dumont, Marcel Van Goethem, 1931-34), Generali (same architects, 1934-36), Ravenstein Gallery (Alexis and Philippe Dumont, 1954-58), former Belgolaise bank (Jean and André Polak, 1952-54), bordered by the Central Station (Victor Horta, 1936-45), Palais des Beaux-Arts (Victor Horta, 1922-29) and Mont des Arts. In the 1930s, the town-planning regulations for these new buildings in these newly redesigned blocks called for commercial ground floors to have large windows and be well-lit at night, to ensure an urban life after office hours.

2.2. THE INNER RING

After World War II, Belgium launched a major initiative to modernise its road network[5], providing Brussels with urban motorways. Such development was spurred on by Expo 58[6]. The redevelopment of the Inner Ring[7], an 8 km stretch of 21 boulevards and avenues transformed into an urban motorway, was inaugurated in 1957. Most of this new building front was given over to office buildings in the dominant International Style : Winterthur (Philippe Dumont, José Vandenbossche, 1954), mutual insurance Prévoyance Sociale (first curtain wall in Belgium, Hugo Van Kuyck, 1954), the iconic bank BBL (Gordon Bunshaft SOM, 1964) (**Fig. 1**), Madou Tower (Robert Goffaux, 1965), IBM Tower (Walter Bresseleers, 1978)[8], …

2.3. INTERNATIONALISATION

The decision to host the European institutions in 1959, and the new NATO headquarters in 1966, established Brussels as the stronghold for office buildings and office districts.

The first emblematic buildings of the European institutions -Charlemagne building (Jacques Cuisinier, 1967), Berlaimont building (Lucien de Vestel, Jean Gilson, Jean et André Polak, 1967)- as well as the axes Rue de la Loi - Avenue du Berlaimont will make up the new 213-hectare European District[9]. Several dozen buildings here comprise a collection of architecturally diverse structures built since the 1967s, embodying real-estate (post)modernism, as well as the stakes of vast real-estate operations and large-scale rehabilitation efforts aimed at breaking the monofunctional character of the district[10].

2.4. PASTORAL CAPITALISM IN THE GREEN PERIPHERY

After the Second World War, the Outer Green Belt developed thanks to an efficient road network combining radial and concentric roads linking these newly built areas to the Inner Ring. Many companies intend to install their new offices in this green and quiet periphery. Development plan no. 6 of Watermael-Boitsfort 1964-67 aims to regulate new constructions and promote high-quality free-standing architectural objects and their integration within the green environment. This area is home to the most emblematic references

10. In April 2024, the Belgian state investment fund SFPIM bought 21 buildings from the European Commission for 900 million €. 300.000 m² obsolete office buildings from the 1960s-1990s to be transformed for 70% into sustainable office space, 30% for commercial, residential and public facilities. https://ec.europa.eu/commission/presscorner/detail/fr/ip_24_2329

of 1960s-1970s corporate architecture in Brussels, including the headquarters of glass producer Glaverbel (designed by Renaat Braem, 1963-67), cement producer CBR (designed by Constantin Brodzki, 1967-70) and the offices of insurance company La Royale Belge (1967-70). These buildings are considered important heritage landmarks and are protected as such.

2.5. "BRUXELLISATION" AND NEW AMBITIONS

The Manhattan Plan drawn up by Groupe Structures in the 1960s to clean up the Northern Quarter was approved in 1967. 53 hectares of urban land were used to reproduce a business district similar to that of New York, linked to the rest of the continent by heliport and motorway. This project involved hundreds of expropriations and demolitions of buildings, as well as the displacement of several thousand residents. Popular protest grew against this "anti-urban" functionalist vision as it was considered the peak of unbridled and traumatic functionalist urban planning known as "*Bruxellisation*". The plan proposed 54 towers, including eight 28-storey World Trade Centre towers. Eventually, with the oil crisis in 1973, the WTC was reduced to three towers (Groupe Structures, 1968-83). In the 1980s and 1990s, the federalisation and regionalisation of the Belgian state resulted in an urgent need for office space that came to the rescue of the Northern Quarter[11]. These buildings are now the target of several innovative renovation scenarios based on sustainability and mixed functions, in line with pressing needs that depend on urban policies. The ongoing ZIN project - the major transformation of two WTC towers with an audacious new building linking both towers - is indicative of the contemporary approach for serial office buildings: retrofitting, circular economy, multifunctionality.[12]

3. A FRAGILE LEGACY AT THE FOREFRONT OF INNOVATION

Today, office buildings may now seem outdated in terms of taste and functionality, but at the time they were built, they represented some of the most innovative architecture on the market. The use of new construction methods (PREFLEX beams[13], curtain wall,…) and new materials (architectural concrete, aluminium, COR-TEN steel, Stopray glazing, sandwich panels, plastics, etc.)[14]. Additionally, they incorporated new techniques, such as ventilation and computerisation, alongside the functional and rational distribution systems. However, the innovative and experimental nature of these buildings weighs heavily on their future. Technology and finishing were becoming increasingly important; structures becoming less and less expensive, to the detriment of the longevity of the building as a whole. In the 1970s, offices became a cost-effective investment product that had to be cheap and flexible, evolving from corporate tropes to a utilitarian, speculative objects, meaning a decoupling of the building's overall lifespan (50 years) from the interior lifespan (15 years). Standardisation, efficiency and market conformity are the focus. In terms of interior layout, most are characterised by a central circulation core surrounded by open plan or partitioned offices (1.8 x 5.4 metre module with a central corridor). The building lifespan (50

11. The 1980 state reform created the regional institutions in Flanders and Wallonia. Brussels Capital Region was officially created in 1989. Urban planning and heritage policies have since been regionalised.

14. "Post-War Building Materials." n.d. Post-War Building Materials. http://postwarbuildingmaterials.be/.

years) and the interior (15 years) were decoupled to make it fully responsive to the market. This resulted in generic office boxes with changeable decors, a literal architectural manifestation of the throwaway culture.

4. AN EMERGING ARCHITECTURAL HERITAGE

The fate of office buildings remains the domain of real estate companies and the private sector.

Some major buildings have already been torn down, such as the hurried demolition in 2001 of the Rogier Tower (Jacques Cuisinier, 1958-61). This urban landmark included offices, shops, passageways, housing, bars and restaurants, exhibition areas, a theatre and bus stops. As part of the redevelopment of the North-South railway junction (Robert Goffaux, 1962-63), the Lotto Tower was demolished in 2003 and rebuilt with eight fewer floors. The Foncolin building (André Jacqmain, 1955-57), which was the first building with an exposed structure and internationally praised, was demolished in 2001 and rebuilt as a postmodern Sapphire in 2003 by the same architect and his Atelier de Genval[15].

On the other hand, urban policy issues and the conservation of heritage and office buildings in particular are matters for the competent authorities and encourage participative involvement of local residents and associations (such as Docomomo.be).

The creation of an autonomous Brussels Capital Region in 1989 gave i.a. new competences in terms of urban planning and heritage management. Urban.brussels, in charge of heritage, urban renovation and building permits, recently focused on a thematic inventory of the built heritage from 1939-1999. Concerning office buildings, the first item -the rectorate of Vrije Universiteit Brussel- was protected in 2007 and is currently being restored respectfully; CBR in 2018 and La Royale Belge in 2019 were listed to save them from irreversible transformation or demolition; BBL bank saw itself as listed in 2021 before the ongoing renovation works; Glaverbel in 2022, garage and D'Ieteren (VW) headquarters followed in 2024.

5. REINVENTING THE OFFICE BUILDING

Aside from their cultural significance, most office buildings need renovation to become sustainable and functional. The regional legislation favours a circular economy with subsidies for adaptive re-use[16], while demolitions are discouraged, due to their high cost and environmental impact. The current policy is to prioritise adaptive re-use to provide affordable housing. The main constraints for transformation into housing are the floor-to-floor height, which often measures less than 3 metres, as well as the depth and accessibility to the vertical circulation core with the elevators and the emergency exits. Other considerations include the need for opening windows, the post-COVID obligation for a balcony for each apartment, accessibility for disabled people, external insulation, and the reuse capacity of structural elements. Around 30% of the office building stock can enter into this category[17]. About 20% of recent new housing is today the result of the older office buildings being

15. Atelier de Genval was founded by André Jacqmain in 1967.

16. "Be.exemplary." n.d. Accessed July 31, 2024. http://beexemplary.brussels/.;"Renolution ! | Renolution." 2024. Renolution.brussels. 2024. https://renolution.brussels/fr.ROTOR Deconstruction & Consulting cooperative company since 2014.

17. Study day April 17 2024 Observatory of Offices, Perspective.brussels.

repurposed. Those interventions significantly alter the outer appearance; for example, adding balconies and outside insulation is often the pretext for a new exo-structure (BASF, The Cosmopolitan (**Fig. 2**), Leopold Views). The typical office building interior configuration consisting of a 1.8 x 5.4 metre module - a 1.8 metre-wide corridor with 5.4 metre deep rooms on either side- can limit the variety of apartment typologies.

But reallocation into housing -not to say social housing- is still more expensive and less profitable than using the space for office purposes. It is even less so as there is still a demand for updated contemporary office spaces. Renovation into the same monofunctional usage is the main reason, with the focus being placed on improving energy performance. Some renovations do take into account the architectural expression if it aligns with the desired image such as in the cases of Generali, CBR, IBM, and PS. However, the question remains as to the degree of 'respect' to be shown for the preservation, for instance, of the lobby and integrated furniture. But most concern the 'generic office boxes with changeable decors' mentioned earlier. They undergo serious retrofitting and redesigning of new façades and interior layouts. Recent legislation requires that new office buildings be previewed in design and materials to be reallocated subsequently into multiple reuse possibilities.

6. LA ROYALE BELGE (1967-70)

Cramped in their historical buildings in the centre of the city, La Royale Belge Insurance Company decided to change its headquarters for good in the 1960s. The company was growing steadily, modern life brought with it new demands to the organisation of its services, and its urban location was now imposing more and more constraints on its activities, and it also required new "branding". After having considered a high-rise building on the Inner Ring, the board bought in 1965 a plot of land of about 8.5 ha in Watermael-Boitsfort at the edge of the Sonian Forest.

Designed by the architects Pierre Dufau (Paris) and René Stapels (Brussels) and landscape architects Jean Delogne and Claude Rebold (Brussels), the building is directly inspired by the John Deere & Company headquarters in Moline (USA), designed by architect Eero Saarinen and landscape architecture firm Sasaki, Walker and Associates (1957-1963). It is characterised by its cross-shaped design and its exposed structure made of concrete beams, COR-TEN steel and Stopray Gold reflective glazing, placed on a large square all-glass base, in the setting of a pond in the middle of a sloping landscaped park. Its design was influenced by the most avant-garde construction methods, materials and technology of that time. The interior is luxurious and modern, focusing on efficiency and employee well-being. The monumental white marble ground floor hosts a large auditorium decorated with an 800 m^2 brass mural, treated by acid dripping, by French sculptor Pierre Sabatier. Thanks to its audacious architecture in terms of its composition, structure, and materials, its integration into the landscape and the quality of its interior design, La Royale Belge is an iconic example of international Corporate architecture. An extension was

© Caruso St John Architects, 2022.

built by the same team of architects in 1983-87, linked by a covered aerial footbridge, which was later demolished in 2020 (**Fig. 3**).

In 2017, there were plans to demolish the building as it sat empty (US embassy). In 2019, the building and its park received official heritage protection as a monument and site, thanks to a spontaneous popular awareness with the support of heritage organizations such as Docomomo.be and ICOMOS. That same year, an international competition for a vast programme of restoration-renovation-repurposing was won by Bovenbouw Architectuur, in association with Caruso St John Architects, DDS+ and MA2. Extensive works (2021-2023) involved a. o. the replacement of all the glazing for energy efficiency reasons and of the non-structural COR-TEN steel elements due to wear and tear (**Fig. 4**).

In spite of this, significant concessions were made in order to strike a balance between new needs and heritage policy. Such changes were thoroughly analysed and validated by the heritage authorities. They included an audacious 'geste' for a new adapted circulation to the new functions (**Fig. 5**), large openings in the original marble walls of the monumental entrance hall for the new restaurant, and supplementary access to the park.

The Mix is a newly inaugurated building that features five levels of offices, three levels of hotel rooms, co-working facilities, wellness areas, bars and restaurants and hosts many events thanks to its restored auditorium. This multifunctional concept is a sustainable contemporary solution to the challenges of reconciling heritage, addressing environmental (EPB) concerns and dealing with economic issues relating to the future of corporate architecture buildings from the second half of the 20th century. ■

PRESERVING THROUGH TRANSFORMING. EXPLORING THE CONVERSION PROCESSES OF EMERY ROTH AND SONS' POST-WAR OFFICE BUILDINGS IN MANHATTAN INTO RESIDENTIAL SPACES

ABSTRACT

Manhattan is currently undergoing a substantial effort to renovate its post-war high-rise buildings. Rather than opting for replacement, the focus is on transforming existing office towers, especially during times of crisis. The renewed interest in adaptive reuse, dating back to the 1990s with the Lower Manhattan Revitalization Plan, blurred the boundary between conservative and transformative approaches to Modern built legacy. Interventions in adaptive reuse have sparked a new phase in the ongoing debate about discovering alternative uses for struggling office buildings.

Despite the considerable attention devoted to factors influencing the conversion of these buildings, such as adherence to urban codes, historical and social significance, and energy efficiency, there remains a noticeable gap in understanding the correlation between fundamental conservative intent that stands on morphological features, and their impact on future transformations within a large building stock.

This contribution analyses and compares the conversion of modern office buildings by Emery Roth, and Sons, initiated in the 1990s, specifically examining the transformation from 110 Wall Street to the recently completed 180 Water Street and the ongoing project at 55 Broad Street. These cases function as pilot studies, providing insight into the ongoing debate surrounding the transformation of non-listed modern office buildings in Manhattan. They offer a critical perspective on the potential alliances between heritage preservation and environmental sustainability through adaptive reuse practices.

This methodological approach encompasses examining morphological features to highlight the transformation process dynamics from an architectural design perspective. This paper offers insights into the adaptive reuse of Manhattan's modernist office buildings, to contribute to ensuring their legacy endures while meeting contemporary demands.

The proposed approach is instrumental in comprehending the intricacies of the potential of conserving through transforming and bridging the gap between history and design disciplines to foster an interdisciplinary framework.

1. INTRODUCTION

Renovating and adapting historical buildings is of paramount importance in the context of climate change as it effectively addresses the urgent need to mitigate greenhouse gas emissions, adapt to a dynamic climate, and simultaneously preserve our built heritage through their continued utilisation. The potential for conversion of office spaces is a matter of analysis in the last decades[1]. Over the last few years, vacancy levels in office markets worldwide have risen to unprecedented levels[2]. At the same time, almost 30 million sqm of office space in the United States is predicted to be obsolete by 2030[3].

In New York City the phenomenon is radical. The city houses the largest office real estate market in the world by area. With more than 42 mln sqm of office space, Manhattan's stock alone is larger than the amount in all other U.S. cities.[4] In the aftermath of the COVID-19 pandemic, the increase in office vacancy rates has reached levels not seen in New York City for several decades. Driven by the rise in home working and general economic uncertainty, Manhattan office space available for rent has increased from 10% pre-pandemic to approximately 20% in November 2022. Moreover, the office building stock is mostly an outdated urban heritage, and approximately 70% of New York commercial tall buildings were built before the 1980s, and will soon need to be replaced or renovated.[5] To address this issue, a massive movement to regenerate Manhattan's high-rise estate is underway.

If building replacement is one of the ways in which New York City responds to typological and functional obsolescence right from the origins of the tall building[6], during times of crisis, the renovation of the existing office building stock to meet emerging needs is a more common choice.

Furthermore, the decline in the use of office space coupled with the urgency of high-demand uses – such as housing – has triggered a new phase of the debate on finding alternative uses for struggling office buildings. The adaptive reuse of office buildings, a field of research that has already been explored in Manhattan particularly since the 1990s, i.e. Lower Manhattan Revitalization Plan[7], in the last year has been strengthened both by private investments and municipal policies. The foundation of the Office Adaptive Reuse Task Force in 2022 constitutes perhaps the most effective action of New York City municipality to support this regeneration movement[8].

However, a combination of legal, logistical, and financial challenges threatens the possibility and profitability of conversions, severely limiting the number of buildings suitable for conversion. This is especially true for modern large-floor plate skyscrapers, whose future is uncertain and at risk. As the first report of the task force points out, the office buildings built after World War II, especially after the 1961 Zoning Resolution, constitute an outdated and rather critical heritage in terms of their transformative potential. Due to both the regulatory system and the architectural typologies, these buildings are generally more difficult and very expensive to reuse.

Drawing inspiration from the shearing layers of change theory, this pivotal research aims to reveal how these buildings can be reconfigured to accommodate new uses[9]. In this paper, we are focusing on the adaptation

challenges related to building morphology from an architectural design perspective to contribute to answering the question "How did these modernist offices learn to be residential?"[10]

To unveil this potential for adaptation of post-WWII office skyscrapers in Manhattan, and its many spatial challenges, we employ a comparative analysis of the morphological features of three office buildings part of the Emery Roth, and Sons' built legacy in Manhattan: 110 Wall Street, 180 Water Street, and the ongoing project at 55 Broad Street.

The cases are discussed by focusing on key morphological features that are highlighted as "critical" in the ongoing debate about office-to-residential conversion in Manhattan. The physical adaptability[11] involves specific design actions focused on their primary features: the façade, depths, and services. This contribution examines typological layout shifts, internal circulation, plan depth, natural light and ventilation strategies, tight and long units, interior partitions, services, amenities, and hybrid spaces.

2. THE LEGACY OF EMERY ROTH AND SONS

Emery Roth and Sons was one of the most prolific architectural firms for office buildings in the Second Post-War Manhattan development boom. From 1947 - when the firm, in its new format, was established - to the late 70s - when reorientation was taken over by a new principal - the design office directed by Richard Roth contributed with more than 100 buildings, mainly speculative office buildings, to the Midtown and Lower Manhattan skyline, with pitches of 10-11 buildings per year[12]. According to a list of the largest architecture firms in New York published by *Crain's* in 1994[13], Emery Roth and Sons buildings accounted for almost 9.5 mln sqm of project space, landing the firm at number 7 of 25.

Working closely with real estate developers - such as the Uris Corporation, Tishman Group, Diesel Construction, Durst Organisation, and Helmsley-Spear, Inc. - they increasingly specialised in commercial space.

Their buildings, mostly pure prism of wedding-cake office towers, were designed with steel and glass curtain walls, and facing plazas, struggling to fit the market requirements for speculative buildings and embodying the sleek, modern, Post-war style.

Throughout its practice, the firm specialised in large-scale design production oriented towards meeting the demands of the real estate market. Consistently, the firm provided designs tailored to meet market needs, skilfully navigating zoning code regulations to maximise the rentable area.

The firm's legacy encompasses a broad spectrum of buildings reflecting real estate demands, ranging from a few iconic landmarks to numerous average market-oriented buildings. However, with some exceptions, these buildings are not considered heritage-listed. As time progresses, typically between 50 to 70 years, many of these office buildings begin to exhibit signs indicating the need for repositioning and potential conversion.

3. CROSSING MORPHOLOGICAL SHIFTS

The selected buildings, including 110 Wall Street, 180 Water Street, and 55 Broad Street, are but a few examples of Roth's office buildings designed between the late 1960s and early 1970s as part of the "new city emerging Downtown"[14], that have undergone or are currently undergoing office-to-housing conversions. Other notable examples could include 200 Water Street and 10 Hanover Square.

The selection is based on their primary design approaches, addressing specific issues that render them relatively prominent in ongoing debates. For instance, 110 Wall Street represents a unique case of hybrid programming, blending co-living and co-working spaces. 180 Water Street serves as a case study for its design approach aimed at resolving challenges posed by large-depth floor plans. Meanwhile, 55 Broad Street stands out as one of the largest office-to-residential conversions in New York City.

3.1. A MATTER OF DEPTH

180 Water Street is a 26-story office building with over 40,000 square meters of space. Completed in the early 1970s, the building underwent a transformative conversion into housing in 2017 under the direction of developers Metro Loft Management and Vanbarton Group. Avinash K. Malhotra Architects served as the main architectural firm, with CetraRuddy handling the interior design[15]. This conversion resulted in the creation of more than 570 market-rate luxury residential units alongside a comprehensive array of upscale amenities - such as 24-hour doorman, a rooftop terrace boasting a pool, a fully equipped fitness centre, a children's playroom, and a tenant lounge.

This case holds particular significance because of the architectural challenge posed by large-plate structures. The considerable depth from windows to the building's core, measuring up to 22 m, presented a huge obstacle, surpassing the ideal depth for conversion into residential apartments. To overcome this challenge, a strategic solution was devised: a 9-by-12 metre courtyard was obtained by digging the building's core. This new open space served multiple purposes, including the introduction of natural light and ventilation to numerous apartments and mechanical areas while minimising the impact on structural columns. Notably, this courtyard facilitated the creation of a double-loaded corridor, with apartments lining both sides, including "studios" with windows facing the courtyard.

What might initially appear as a bold and expensive move is, in fact, grounded in careful economic analysis and strategic planning. By taking advantage of zoning regulations relaxed in the 1990s to encourage conversions in the financial district, the developers seized the opportunity to convert the entirety of the building's floor area into housing. The inclusion of the courtyard effectively compensated for the space lost from the building's centre, enabling the addition of floor area — and consequently, additional rental income — to the building's upper levels, turning a 26-story office building into a 30-story apartment building. This approach extended to the

rooftop, where modern amenities such as a pool, rooftop deck, gym, and other facilities were seamlessly integrated, further enhancing the appeal and functionality of the revitalised structure.

3.2. A MATTER OF INTERIOR RATIO

110 Wall Street, a 27-story, 20.000 sqm building designed by Roth's firm, opened in 1961. After Hurricane Sandy caused significant damage in 2012, owner William Rudin was forced to cancel office tenants' leases and reconsider the building's future[16]. Almost a year later, WeWork took control of the building, transforming it into the first "WeLive" co-living space, with ARExA and Perkins Eastman S9 leading the design[17]. WeLive proposed a community-driven concept aimed at young renters seeking a sociable lifestyle. The adaptive reuse project resulted in a mixed-use building that combines neighbourhood-oriented retail and food/beverage options with collaborative workspaces, on the 5-story building base and a progressive

17. Matthew Haag, Rebecca Liebson, Andrea Salcedo, "WeWork Planned a Residential Utopia. It Hasn't TurnedOut That Way", *New York Times*, Oct. 13, 2019; Stephen Smith, **"**Permits Filed: 110 Wall Street's WeWork-Led Mixed-Use Conversion", *New York Ymby*, Dec. 9, 2014; Michelle Cohen, "WeWork's Communal Living Concept on Wall Street Gets Its First Residents", *6sqft*, Jan. 13, 2016.

new residential concept for the upper floors. The conversion features 205 fully furnished and serviced residential units, designed mainly for short-term rentals and to reduce costs for residents by sharing space, similar to WeWork offices.

Billed as a "disruptive alternative to the way people live" and "Nirvana for Millennials," the WeLive experiment received both criticism and praise, earning mentions in several newspapers, including Time magazine[18].

The architectural reuse incorporates studio, one to four-bedroom units, integrated with collective spaces like kitchens, lounges, and bathrooms. Large communal areas and redesigned staircases, extending into small lounge spaces on various floors, foster resident interaction.

Despite the current challenges of the building's manageable depth, internal circulation, and space usage, it has led to narrow, long residential units - with an average area of 40 sqm - with limited natural light in the inner part. The interior spaces are reconfigured to include study areas, storage, and sleeping alcoves on the unit's windowless side. This conversion could be seen as a modern reinterpretation of the 19th-century railroad apartment model, offering (upscale) accommodation for young professionals. Architect Avinash Malhotra, experienced in office-to-residential conversions, notes that such projects often transform office towers into numerous small units, humorously referring to them as "slums for the rich."[19]

3.3. A MATTER OF FACADE SYSTEM

The former Goldman Sachs headquarters at 55 Broad Street, which opened in 1967, has seen its occupancy levels drop to just 60% due to the rise of remote work since 2020. Acquired by Silverstein Properties and Metro Loft Management, the almost 40.000 sqm building is now undergoing a major transformation designed by Cetra Ruddy Architects[20]. Construction began in the summer of 2023 and is expected to be completed by 2025.[21]

Similarly to the approach taken with the 180 Water Street project, architects at 55 Broad Street are converting commercial space into residential use by reclaiming floor area, thus allowing for additional square footage at the top of the building. At 110 Wall Street, however, the setback design posed programmatic challenges, especially on the lower floors with longer lease spans, requiring some apartments to be deeper than typical residential units. Despite these challenges, the setbacks facilitated the creation of a variety of apartment sizes and types, ranging from efficient units to loft-like layouts with generous terraces. The depth issue was ingeniously addressed by incorporating flexible spaces or home offices near the building's core, a highly desirable feature in today's remote and hybrid work environment. Additionally, the setbacks allowed for the inclusion of terrace spaces for select units.

Despite the shape differences with 180 Water Street and programme differences with 110 Wall Street, a common challenge remains: rethinking the curtain wall. Glass curtain-wall facades, characteristic of modern American skyscrapers, must be adapted for residential use by incorporating

operable windows, significantly increasing conversion costs and altering the original facade's linear appearance. However, this adaptation encourages energy-efficient approaches to climate management, replacing forced air conditioning with openable, customisable systems. This shift aligns with the concept of "After Comfort," promoting a change in expectations for internal thermal comfort.[22]

4. CONCLUSIONS

The conversion of post-World War II office buildings to residential uses raises important questions about the intertwining of preservation and transformation of modern architecture.[23] This is particularly true for skyscrapers designed by Emery Roth and Sons, which form part of Manhattan's 'ordinary'[24] architectural fabric but face uncertain futures without the protection of heritage preservation agencies. Converting office spaces to residential use helps mitigate the risk of abandonment and decay caused by low occupancy rates. However, these transformations frequently entail substantial alterations to internal circulation, curtain walls, and sometimes structural elements, posing challenges to conventional concepts of modern architectural preservation.

A second issue concerns the urban role of modern architecture. As Robert Stern stated in a 1996 Times interview, "Who doesn't want to live in a skyscraper?"[25] Although office buildings are not typically considered the main solution to the housing crisis, their conversion has a notable impact on the use and perception of modern urban structures. Such transformations can foster cultural diversity through mixed uses and diverse resident profiles, keep buildings and neighbourhoods vibrant beyond office hours, and repurpose ground floors from lobbies to communal spaces and services. This "city of quantity" prompts a re-examination of the relationship between preserving memory, promoting sustainable development, and adapting to new uses, not as opposing forces but as parts of a unified process in a world where "preservation is overtaking us."[26] ■

BIOGRAPHY

Caterina Barioglio is an Assistant Professor at the Department of Architecture and Design at Politecnico di Torino. She earned her Ph.D. in History of Architecture and Urban Design in 2016, conducting her research between Turin and Columbia University in New York City. Bridging the realms of history and design, her work focuses on urban transformation processes and the pivotal role of architecture in urbanisation. She is a fellow at the interdisciplinary research centre Future Urban Legacy Lab. She is an editor for Ardeth - Architectural Design Theory Journal.

Elena Guidetti is an Architect and a post-doc research fellow at the Future Urban Legacy Lab research centre at Politecnico di Torino. In 2022, she earned a Ph.D. in "Architecture. History and Project" at Politecnico di Torino with a thesis on the transformative potential of existing buildings in post-functional Europe. Since 2018, she has been lecturing and collaborating with the Politecnico di Torino, the Universities of Ferrara, Hasselt, Sarajevo, and Tirana. Her work focuses on the adaptive reuse of buildings following a morphological perspective based on stages of completeness and embodied energy.

TYPOLOGICAL EXERCISES AND THE SINGULARITY OF ITERATION

MAXIMIANO ATRIA
UNIVERSIDAD DE CHILE

ABSTRACT

This article explores the development of modern architecture by examining its engagement with typology, emphasising the search for new forms that reflect contemporary society. Rooted in the Industrial Revolution, modern architecture sought innovative solutions to urban challenges while adhering to established typological constraints. It delves into how architects, inspired by the transformative energies of modernity, created a diverse range of typologies, such as schools, airports, and gasometers. Each typology embodies both repetition and singularity, demonstrating that even within constraints, architecture can achieve remarkable creativity and innovation. The article discusses several case studies, including Bayardo's Ossuary, Von Schmidt, Aicher, and Heifer's gasometers, mat-building schools in Brazil, and mid-sized airports in Chile, illustrating how these structures transcend typological boundaries. Ultimately, it argues for a reevaluation of modern architecture's legacy, emphasising the richness found in iterative design processes that balance tradition with contemporary needs.

One of the key expressions of modern architecture was its exploration of new forms and dispositions that would constitute what modern architects referred to as the expression of the times. This search for new forms was viewed as an opportunity for new propositions and professional development, and it accompanied the Industrial Revolution by giving physical form to buildings and facilities that required new dimensions and materials. As is common in architecture, they had to work within the constraints of typologies. What started out as the pursuit of a small group of architects in the early days had a global impact in what could be described as a modern culture that sprang up in different countries and cultures where the energies of modernity were assumed by inspired architects. As modernity changed the old ways of working, moving and living, architects had to devise new solutions to old and new challenges. In that sense, the vast majority of architectural typologies are not modern but are part of a long human history. When new programmes had to be created ex-novo, like the airport, new typologies were created as "containers" of constraints to meet the demands of apparent absolute freedom.

Typology, though, is not unique to modern architecture: the classical world had numerous typological series, and in a way, it made the development of types a key factor in its success. The Greek and Roman worlds introduced the first concept of a true "international style." The repetition of forms and functional dispositions was seen as the embodiment of the true spirit of the times, as expressed in architectural form. In the 20th century, this idea of iteration spurred modern architecture to experiment with new forms and materials. The text provides a representative (although obviously incomplete) set of typologies: the school, the airport, the cemetery and the gasometer. Additional examples could include the hospital, the prison, the church or the temple, the grain elevator, the house, the residential complex, the office building, and so on.

The history of modern architecture and catalogues of practising architects are filled with particular expressions of typologies—these and others. But what is in a typology? What can we learn from this iterative system where design freedom is constrained by the very limits of what makes a typology what it is? First, a typology has a name, a generic title that encapsulates and allows us to understand the essence of form even before we set our eyes on the drawings or photos of a specific building. We have come to identify what we can expect when we encounter, for example, a gasometer. In such a case, it has a certain size and shape attached to its name. And we know that there are gasometers all around the world and that they follow these same rules of shape and size, but they are all, in their own way, different.

That is the singularity of iteration. It is the notion that within the confines of repetition, every building of a certain type retains a singularity specific to its location, the identity of its creator, and the circumstances (historical, social, political, economic) surrounding its design, construction, and eventual demolition. These unique elements allow us to be surprised by

special and extraordinary details in a Gothic cathedral, a Greek temple, or a Haussmannian building in Paris.

Centring on this singularity, we can move away from the usual critiques made of modern architecture (such as being boring, always the same, or lacking creativity, etc.) and instead begin concentrating on the details that make it rich.

In this session, we have four representatives of architectural typologies. Each of them breaks free from the constraints of its type and showcases stunning creativity, whether it may be in the details or in the systemic organisation of the programme. What makes them noteworthy is also that they show how architecture can be interesting just by expanding its propositions without being forced to establish new patterns at all times. Architects design within the definitions of a culture and along a historical continuum to which they belong or against which they can revolt.

Bayardo's Ossuary (1959-1962), as presented in the paper by Jorge Gambini, is rooted in the history of funeral architecture, the above-ground cemetery, a typology adopted by modernity due to specific constraints related to urban and economic conditions. It is an extension of the more ancient mausoleum or the underground cellar for reduced tombs, similar to the Paris catacombs, but taken from its individual purpose to the scale of a building. Perhaps a sub-typology in itself, it incorporates several leitmotivs of modernity to compensate for the iterative conditions of the commission, and the result is surprisingly unique. It is true that the sacred has given modern architecture the pretext for some of the most magnificent bursts of creativity and mastery from architects around the world (from Le Corbusier's Ronchamp church in France to Itala Fulvia Villa's Chacarita cemetery in Argentina, to name just two). In this sense, modern architecture simply follows a historical trend, implying that when energy is devoted to the service of the spiritual world, we see architectural masterpieces that transcend the passing of time.

Von Schmidt, Aicher and Heifer's gasometers (1896-1899), presented by Markus Tomaselli, are a typology in themselves. There are four of them, emphasising the notion of iteration. They are strong expressions of the Industrial Revolution and the new technologies that were put to the service of modernity in fin-de-siècle Europe. They are an example of the historical continuity of what has become one of Docomomo's leading occupations: adaptive re-use. The obsolescence of technology is just a pretext for the reutilisation of the buildings that housed them when societies look for the preservation of collective memory and the reduction of contamination and energy waste due to demolition. Another sub-typology can be found here, that of the re-used facilities of industrial infrastructures, such as recycled grain elevators turned into apartment complexes. Tomaselli defines the project as "a testament to the innovative spirit of adaptive reuse and sustainable design," illustrating contemporary architects' efforts to bring new uses to historical structures. Some of these actions required alterations to listed buildings, giving way to the debate on the limits of legal protection

and how accepting alterations can help preserve obsolescent structures by projecting new forms, uses and materials onto them.

Mat-building schools in Pernambuco, studied by Leao and Moreira in their paper, introduced a new consideration to the concept of typology. They highlighted the systematisation of the design process, emphasising a typology of action rather than function or form. They presented the idea that mat-building is a way of designing, rather than a repetitive form dedicated to a specific function. It was suggested that we could list the cases that fit within the typology of buildings designed using the mat-building conception, which has been described as a system rather than an aesthetic, where typology operates on several levels. There is the systematic organisation of a programme financed by the United States to strengthen the educational system of Brazil (as has occurred in other Latin American countries due to the "good neighbour" policy), the school in itself as a typology that we can follow along historical and geographical lines, and the mat-building way of designing. The extraordinary forms that emerge from a simple system based on rules of design are a demonstration that the boundaries set by a typology give the architect more freedom.

Last but not least, Cvitanic and Galeno, in their paper on the airports built in mid-size cities in Chile, demonstrate how locally adapted conditions can enrich a typology by stressing the tension between the changeable and the permanent. A programme so defined by use and by the flux of people and goods like an airport can, in the hands of a skilled architect, become an expression of typological creativity despite the apparent contradiction.

All these cases focus on typology. Hundreds of other cases could be added to each selection presented here. As illustrated earlier, typology and iteration are fundamental elements of architecture, likely responsible for transforming a simple way of constructing shelter into a culturally specific human activity and, eventually, a tradition. In this sense, singularity must not be considered a value in itself, as creativity is not limited to unique and extraordinary designs. On the contrary, when viewed as a manifestation of design freedom within the constraints of typology or tradition, even the most repetitive designs can attain a higher level of quality. ■

BIOGRAPHY

Maximiano Atria, born in Santiago de Chile 1972, is an architect who graduated from Pontificia Universidad Católica de Chile. He holds a Master's in Architecture and a PhD in Architecture and Urban Studies from the same university. He also possesses a PhD in History from the Ecole des Hautes Etudes en Sciences Sociales (EHESS). A founding member of Docomomo Chile, he served as its general secretary between 2004 and 2020. Atria is an associate professor at the Faculty of Architecture and Urbanism of the University of Chile and has been a visiting professor at the Ecole Nationale Superieure d'Architecture Paris-Malaquais, and at the Ecole Spéciale d'Architecture in France. He is also director of the cultural management agency La Oficina, specialising in projects related to the field of the city and architecture. In 2017, he curated the exhibition "Le Corbusier y el Sur de América," which featured 55 original drawings and plans by the French architect for projects in South America.

THE CONFINES IN THE ARCHITECTURAL TYPE DEFINITION: THE MODERNITY OF AIRPORT TERMINALS IN THE EXTREME REGIONS OF CHILE

ABSTRACT

The 20th century witnessed a significant evolution in global aviation, leading to the emergence of airport terminals as a new architectural typology aligned with the Modern Movement. This development, considered crucial for migration and the spread of technical knowledge and modern ideas between peripheries and centres of power, had a notable impact on Chile, an extremely elongated and confined country.

During the second government of Ibáñez del Campo, airport architecture became institutionalised in Chile through the National Aerodromes Plan implemented from 1954 to 1956. This programme aimed to connect the confined ends of the country with the centre by implementing runways and suitable infrastructure for the technological advances in aviation. The execution of this plan led to the emergence of a new modern architecture developed by the Ministry of Public Works up until the 1970s.

Around 1956, emphasis was placed on airport construction at the extremities of the territory, notably Chabunco in Punta Arenas and Chacalluta in Arica, followed by El Tepual in Puerto Montt and Cerro Moreno in Antofagasta.

Despite aviation's historical and technical relevance and its impact on territories, the architectural expression of airports has received less attention, except for specific references.

The analysis of public archives, press, and institutional memories has been crucial for reconstructing and understanding the evolution of these projects and their use as public spaces, revealing their historical and social meanings and significance. Initially, the first air terminals in remote areas became identity markers. They were not merely connection points but represented gateways to modern life, witnessing the activities of travellers and significant social and political events.

1. INTRODUCTION[1,2]

The 20th century witnessed a significant evolution in aviation, leading to the emergence of airport terminals as a new architectural typology, on a global level. Due to its association with technological progress, this typology was linked to modernity and, architecturally, to the Modern Movement.[3]

Aviation has generated significant attention in historical and technical terms,[4] while its architectural expression has not enjoyed the same level of attention.[5] In Chile, the situation has been similar, and historical perspectives[6] have not been accompanied by architectural, territorial, or urban approaches, except for specific mentions,[7] discussions of their materiality,[8] or contemporary projects.[9]

In Chile, the consolidation of an aerodrome system was institutionalised during the second government of President Carlos Ibáñez del Campo (1952-1958). At that time, a plan was established to connect the entire country functionally and, particularly in symbolic terms, link the remote regions with the centre. The National Aerodrome Plan was an ambitious initiative to provide standardised infrastructure suited to aeronautical requirements, new aircraft and technological advances across a large part of the national geography.

Due to their strategic value, the first terminals projected were those in the extreme areas. Thus, the plan developed by the Ministry of Public Works (MOP), consisted of planning, designing and constructing the airports of Chacalluta in Arica, Cerro Moreno in Antofagasta, and Chabunco in Punta Arenas. Generally, projects were made up of two stages. The first focused on planning the complex, including runways, taxiways, and expansion areas and the second centred on designing the main facilities, such as the operations building, control tower, cargo hold, and passenger terminal.

It is hypothesised that the development of airport projects in the extreme areas of the country established the passenger terminal building as an unprecedented architectural typology in Chile. Its technical requirements, uses, and spatial configurations coincided radically with the principles of modern architecture.

The general purpose is to investigate the first passenger terminals projected in the extreme regions in the context of the National Aerodrome Plan, which was established from the 1950s to the 1970s.

For this research, several archives and libraries have been consulted, including: the General Directorate of Civil Aeronautics, the National Aeronautical and Space Museum, the National Archive, and the National Library; as well as certain local sources. These included the Historical Archive of Arica's Municipality, the Vicente Dagnino Historical Archive (UTA), the Arica Municipal Works Directorate, the Antofagasta Regional Directorate of Airports (MOP), the Isaac Arce Library of Antofagasta's Municipality, El Mercurio de Antofagasta, the Gabriela Mistral Municipal Library of Punta Arenas, and the Magallanes Regional Directorate of Airports (MOP), among others.

In turn, surveys and records of the terminal buildings were conducted, complemented by the review of bibliographic sources on the subject. Through

this integration of approaches, historical and archival information was cross-referenced with the materialisations implemented, addressing the initial assumption, interpreting the problem in question, and refining the reflections.

2. THE NATIONAL AERODROME PLAN

The National Aerodrome Plan was, in reality, a bill presented by the government of Carlos Ibáñez del Campo to modify the aeronautical institutional framework, establish financing, and facilitate the formulation and construction of infrastructures of various conditions and sizes for the establishment of a nationwide air communication network.[10] The Law established the creation of the Permanent Board of Aerodromes and an Airports Department, which would be under the MOP. The Board would be responsible for the annual approval of the Plan, while the Department would prepare the respective projects and execute the works.[11] However, the runway projects were prepared by the MOP Highway Directorate.[12]

The initial MOP plan determined the need to build seventy-four airports in three categories: international,[13] national,[14] and regional/emergency.[15] In this regard, the guidelines of the International Civil Aeronautical Organisation (ICAO) around 1951 highlighted the need to address the planning, design, operation and equipment of aerodromes, areas that were institutionalised in Chile only in 1956.[16]

Due to technical and economic factors, particularly the Valdivia earthquake of 1960, the plan underwent modifications that led to a shift in priorities. Consequently, for geopolitical and practical reasons, priority was given to the extreme regions. Thus, the construction of regulated runways in Antofagasta (1954), Punta Arenas (1956), Arica, and Puerto Montt (1958)[17] were followed by terminal projects in Punta Arenas (1956), Antofagasta (1959) and Arica (1960).

Precisely, in 1959, in an article written by the architect Gonzalo del Canto, the MOP Architecture Department explained the technical aspects involved in the planning of an airport project.[18] The document highlighted the selection of the land for constructing buildings, the building area consisting of the passenger terminal area and the terminal building (in addition to airline and cargo hangars), and the operations system. The text introduced three projects:

the Cerro Moreno airport terminal in northern Antofagasta, the Chabunco terminal in southern Punta Arenas, and the expansion of the Cerrillos terminal in Santiago.

.

3. ARICA: CHACALLUTA AIRPORT TERMINAL

In Arica, the aerodrome used until the 1950s was El Buitre, located on the hills southeast of the city. The region's growing population, its strategic location between Antofagasta and Lima, along with its role as a traditional crossing point to Bolivia, its border situation, and the enormous national and international air traffic[19] necessitated a new airport. Thus, a new facility was constructed in the Chacalluta sector, north of the city.[20] This new airport

13. Eight A category international airports (capable of receiving DC-8 aircraft). With 2,500-metre-long concrete runways: Chacalluta (Arica), Cerro Moreno (Antofagasta), González Videla (La Serena), Pudahuel (Santiago), Hualpencillo (Concepción), Tepual (Puerto Montt), Balmaceda and Chabunco (Punta Arenas).

14. Eleven national airports, with paved or asphalted runways 1,500 metres long, for regional routes and national service landings. It was expected that these would have navigation aid equipment, allowing day and night operation. These would be: Iquique, Copiapó, Ovalle, Valparaíso, Chillán, Los Ángeles, Victoria, Temuco, Valdivia, Osorno and Castro.

15. Fifty-five regional aerodromes, with paved or stabilised material runways. It was expected that they would be enabled to serve as emergency airfields for aircraft operating national routes.

featured a category C runway, 2,200 m long and 45 m wide, suitable for international flights as per ICAO standards,[21] which was completed by the company Longhi y Cía. Ltda. in November 1958.[22]

Subsequently, the project for the passenger terminal **(Fig. 1)** was carried out by architect Gonzalo del Canto,[23] from the Studies Department of the Architecture Directorate of the MOP[24] in August 1960.

The terminal was designed as an elongated two-story prism, measuring 24.7 m wide by 87 m long and 6.5 m high. It runs parallel to the runway, with the control tower extending by 5 meters from the southwest end. It included three areas with differentiated functions: the largest for passengers, a court service area, patio and covered parking, and the operations area at the base of the tower.

Upon entering, and crossing the threshold beneath a marquee, one would step into the central hall, a huge double-height space, surrounded by circulations that accentuated its spatial and visual display. This would be a very significant space, which would host the public activities that would take place in the building.

In October 1964, with construction still underway, President Jorge Alessandri held a symbolic inauguration of the airport.[25] The final inauguration took place in July 1965, with the visit of President Eduardo Frei, returning from an extensive tour of Europe. On this occasion, the architecture was described as "imposing and luxurious", and it was considered one of the best air terminals in the country.[26]

In this sense, a photographic record from the time showed the impact and use of the terminal,[27] particularly its versatility as a new hub for the transit of modern life. It was the perfect stage for massive events that required large public spaces of apparent freedom, coexisting with the absolute and necessary control of bodies and their mobility determined by the aeronautical authority.

4. ANTOFAGASTA: CERRO MORENO AIRPORT TERMINAL

Antofagasta has been a fundamental port in the vast mining region in the Atacama Desert. Due to its historical significance and strategic location, it became an important stopover point on international route stopovers for airlines such as Panagra and the Chilean LAN (National Air Line).[28]

Initially, the Portezuelo airfield and later the Chimba aerodrome, established by LAN to the north of the city in 1941, served as the main landing points.[29] Later, on November 18, 1954, a new mixed-use airport was inaugurated. It featured a runway measuring 2,500 m long and 50 m wide, suitable for continuous commercial and military operations, but still lacked a passenger terminal.[30]

In 1959, architect Gonzalo Rudolphy from the MOP Architecture Department developed a terminal for the Cerro Moreno airport which remained unbuilt. The design included 5,140 square meters and was conceptualised as an elongated two-level prism, a terrace roof, and a control tower above it. The regularity of the main volume was interrupted by a projected staircase and a marquee defining the main entrance, which also

served as a balcony and circulation space, allowing for access to the deck and providing views of aircraft and passenger movement.

Subsequently, in November 1969, architect Jorge Patiño, who was working at CONEST (Construction and Stability Ltd.), developed a new and larger terminal project **(Fig. 2)** for the Studies Department of the Airports Directorate of the MOP. Construction of the project began in 1970.[31]

Although the project was confined to a volume measuring 48 m wide by 108 m long, the control tower stood out as an isolated element with a differentiated expression. The project zoning thus included passenger handling, cargo, and services in the main structure, while operations were housed separately in the control tower.

From a technical perspective, the steel roof was notable. It consisted of two suspended one-metre-thick plates made from coated stereometres, supported by hollow steel beams and expressive concrete columns. The elevated walls, placed parallel behind the columns, formed a large glass volume that contained a shaded space, facilitating seamless connections with the desert landscape and the runway with the aircraft.

The extensive roof planes, the expressive nature of its structure, and the distinctive control tower accentuated its monumentality and emphasised its isolated presence in the desert.

5. PUNTA ARENAS: CHABUNCO AIRPORT TERMINAL

The strong winds of the southern region necessitated the construction of an airport with three intersecting runways, arranged in an "A" shape, determining the location and arrangement of the buildings in an overall proposal developed by the MOP Planning Directorate in 1955. The proposal involved merging four blocks into a single structure through a glazed gallery, incorporating a cargo warehouse, the airport building (serving as the passenger terminal), the operations building (which included the control tower), and the Meteorological Service and Radio Station.

The project **(Fig. 3)** formulated in 1956[32], utilised a reinforced concrete structural module, measuring 4 m in its longitudinal direction and 7 and 8 m in the transversal direction. This module was used for sections of one level, and two levels, and to vertically form the control tower. A curved roof with small inverted eaves was placed on top of this module. Remarkable features of the complex were the access points defined by marquees made of concrete slabs with irregular contours.

The layout of the central block (airport building) was organised with passenger reception, baggage control, offices, and wet areas on the first level. Meanwhile, the second level featured a series of bathrooms, a cloakroom, a bar, a kitchen, and rooms for service personnel, including bedrooms and a large living room. The visual and functional connection between the two levels was achieved through a central double-height distribution space.[33]

In the operations block and control tower, offices were located on the first, second and third levels, while equipment was installed on a fourth level and the control tower on the fifth floor. Meanwhile, at the end of

31. Construction was interrupted by the military coup of September 1973, and was completed in 1975.

32. It was developed by the architects Augusto Iglesias, Gonzalo del Canto (Head of Workshop) and Humberto Gramegna (Head of Studies), from the Studies Department of the Directorate of Architecture of the MOP.

33. Boris Cvitanic-Díaz and Pilar Fernández-Hechenleitner, "Aeropuerto y arquitectura moderna, una tensión entre global y local: el caso de Punta Arenas," *AUS*, 33 (January, 2023): 85-95.

the complex was the Meteorological Service and Radio station, with dormitories for staff on duty.

The project underwent significant modifications between 1967 and 1969[34] when the central block was expanded to accommodate increased demand for flights, cargo and passengers. This transformation did not significantly alter

34. It was developed by the architects Francisco Torres, Ricardo Fernández and Jorge Patiño González (Head of Workshop), from the Studies Department of the Airports Directorate of the MOP

the building's zoning, which was based on simple access sequences from the vehicle to the plane for passengers and luggage, as well as a sectorisation of the building between the first floor, dedicated to the entry and control of passengers and cargo, and the second, dedicated to waiting and observing the boarding, take-off and landing of aircraft. However, the expansion did alter the building's appearance, obscuring the structural framework with a new façade around the perimeter of the first level.

6. CONCLUSIONS

The National Aerodrome Plan, conceived and centrally developed in the country's capital but executed at its extremities, aimed not only to establish connectivity between different regions but also to introduce a new architectural type through modern architecture, creating a unified and recognisable national image.

Implementing these facilities directly led to the emergence of a new architectural type in Chile. This type was subject to changes and adaptations due to varying geographical and climatic conditions, as well as evolving operational requirements over the years. Notably, the functional and volumetric design of the control tower varied in the three locations: it was compact in Arica, divided in Antofagasta, and compartmentalised in Punta Arenas.

This diversity in responses, despite the standardised global technical requirements for air navigation services, underscores how projects adapted to local conditions, reshaping the architectural type.

As a result, the airport terminals evolved into architectural and symbolic spaces of representation, creating a tension between global modern life scenarios and regional characteristics, and defining specific local places.

Airports in general, and particularly those built in the extremes of Chile, reflect both global and local challenges as well as the changes they undergo due to natural obsolescence. However, their status as significant and distinctive landmarks within the constitution of territories is noteworthy. Given their significance and the tendency for these structures to be transformed or replaced due to evolving aeronautical needs, documenting, preserving, and enhancing them is vital. ■

BIOGRAPHIES

Boris Cvitanic-Díaz is an architect with a Master's in Theory and History of Architecture and a PhD in Architectural Projects from Universitat Politécnica de Cataluña. His research focuses on the history of architecture, industrial heritage and modern architecture in the Magallanes region (Chile). He serves as an Associate Professor at Universidad de Magallanes's School of Architecture and has directed research projects for the National Research Agency (ANID) and the Ministry of Culture, Arts and Heritage (MINCAP). He is the author and editor of books in the discipline.

Claudio Galeno-Ibaceta is an architect with a Master's and a PhD in Theory and History of Architecture from the Polytechnic University of Catalonia. His research focuses on the relationship between human body knowledge and architecture, particularly in northern Chile's healthcare buildings. He is currently an Associate Professor at Escuela de Arquitectura of UCN and the director of the School of Architecture. As General Secretary of Docomomo Chile, he has been involved with Docomomo International since 2004. He is also a member of the Ibero-American Association of Urban History. FLEXIBILITY IN SCHOOL ARCHITECTURE: THE 1970S MAT-BUILDINGS OF RECIFE, BRAZIL.

LARISSA MORGANA LEÃO SILVA DE SOUSA
FEDERAL UNIVERSITY OF PERNAMBUCO (UFPE), BRAZIL

FERNANDO DINIZ MOREIRA
FEDERAL UNIVERSITY OF PERNAMBUCO (UFPE), BRAZIL

ABSTRACT

Under pressure to improve basic education, Brazil promoted a broad expansion of the public-school network in the 1950s and 1960s. However, since educational policies were state-implemented, regional gaps persisted, particularly in the north and northeast. During the military regime (1964-1985), the government took on a more active role in funding state programmes, with the technical and financial support of the United States Agency for International Development (USAID). From the late 1960s onwards, this movement led to the mass construction of school buildings with the incorporation of rationalist techniques aiming for economy and speed in the construction process. This resulted in the construction of remarkable buildings, that historiography has yet to fully explore, such as those built in the State of Pernambuco in northeastern Brazil in the 1970s.

This article analyses school buildings in the Metropolitan Region of Recife in the 1970s, guided by MM Roberto's principles for schools in impoverished areas of Brazil's Northeast. It highlights how some of these schools align with Alison Smithson's mat-building concept and effectively employ flexibility principles.

1. INTRODUCTION

Under pressure to improve basic education, the 20th century witnessed a broad expansion of the Brazilian public-school network. However, since educational policies were state-implemented, regional gaps persisted, particularly in the north and northeast. During the military regime (1964-1985), the government took on a more active role in funding state programmes, with the technical and financial support of the United States Agency for International Development (USAID).

From the late 1960s onwards, this movement led to the mass construction of school buildings with the incorporation of rationalist techniques aiming for economy and speed in the construction process. During this period marked by Modern experimentation, architecture of great significance to this historiography was produced.

This article studies the role of flexibility in modern school architecture in Pernambuco, a state in northeastern Brazil. Flexibility is understood as a building's ability to accommodate necessary changes, whether these may arise from shifting user needs or evolving social standards.[1]

The flexible schools of Pernambuco in the 1970s were designed following the guidelines proposed by MM Roberto Architects in 1972. Their compositional strategies were aligned with the so-called mat-buildings, a concept created by Alison Smithson (1928-1993) to designate structures formed by the joining of courtyards, covered paths, and spaces for gathering. The concept was centred on grid organisation, based on connections, associations in the mesh, and possibilities for transformation.[2]

This programme resulted in fifteen schools of different educational levels, as indicated by Loureiro (2000).[3] Within this sample, some examples are quite adept at the concept of mat-building, incorporating some adaptations to the local climate, such as open circulation and the distribution of school space within an organisation by branches, not always conforming to conventional enclosed European school projects.

Initially, the article discusses the origins rooted in the Brazilian educational reform before addressing MM Roberto's guidelines for schools in impoverished northeastern areas. Finally, it delves into the production of flexible schools in the Metropolitan Region of Recife, analysing various school projects, and how they incorporate flexibility and align with the concept of mat-building.

2. PREMEM

Established in 1968, the Programme for the Expansion and Improvement of Secondary Education (PREMEM) was funded by the United States Agency for International Development (USAID) as part of a larger programme to develop educational plans for five northeastern states, including Pernambuco.[4]

The PREMEM aimed to "encourage the quantitative development, structural transformation, and improvement of secondary education".[5] PREMEM's action would enable the expansion and improvement of the public secondary education network through implementation of state-developed plans supported by educational technical assistance.

5. José Arapiraca. *A USAID e a educação brasileira: um estudo a partir de uma abordagem crítica da teoria do capital humano*. (Rio de Janeiro: Fundação Getúlio Vargas, 1979).

The programme ended in 1976 due to financial issues, as a result of the costs of construction and maintenance of the schools, as well as the salaries of their now specialised staff. Another reason for the programme's end was tied to the non-implementation of compulsory professionalisation at secondary level, leading to its abandonment in the early 1980s.

3. THE EDUCATIONAL POLICY IN PERNAMBUCO

Education in Pernambuco has been precarious since colonial times, and it has always been subject to the political whims of local elites. The demand for public schools significantly outstripped supply, particularly with the population growth experienced in the capital, Recife.

In 1964, with the establishment of the Military Dictatorship, one strategy for consolidating the new regime was the establishment of greater administrative control over the federated states, particularly in Pernambuco, known for its emerging social movements. In this context, education became the means that would help both the materialisation of the political project and the imposition of control through the attempt to consolidate ideological control.

Between 1968 and 1971, a set of educational policies and discourses were structured to praise vocational education. This was because the Regime sought to link the need for progress to forming a workforce. With the Education Reform of 1971 for primary and secondary levels, a model of compulsory professionalisation was imposed.

The state's education bases mirrored national demands, including the necessary restructuring to implement a new educational project with multi-purpose gymnasiums. This new model would guide the production of Pernambuco's school architecture in the 1970s.

4. GUIDELINES FOR FLEXIBLE SCHOOLS

Following the provisions of PREMEM, the architects Maurício and Márcio Roberto developed guidelines for multipurpose gymnasiums in impoverished areas of the Northeast, which were published in 1972 **(Fig. 1)**.

The type suggested by the architects resulted from using a modular system in the sizing, structure, and composition of the school building. The module started from the classrooms, each with a capacity for thirty-five students, at a ratio of 1.2 m^2 per student. This proportion led to the demand for large plots of land that would allow for accommodating a greater number of rooms and offer the possibility of extension.[6]

The proposals demonstrate alignment with the so-called mat-buildings. Initially, there is a common juxtaposition of uncovered internal spaces, covered spaces, and circulations. The architects' guidelines emphasise the freedom of placement of these elements according to the pre-existing trees. The guideline does not break with the general proposal of multifaceted extension but rather makes the form less predictable, allowing for better use of local conditions.

Despite the apparent standardisation of plans, this policy permitted vernacular features and elements of local tradition, such as exposed brick

6. Loureiro, *Classe, controle, encontro: o espaço escolar.*

and a four-slope ceramic tile roof. These features are closely aligned with those suggested by Armando de Holanda, in his 1976 *Guidelines to Design in Northeast*,[7] which were very popular among local architects, including those designing schools. His guidelines advocate the use of ceramic elements, ventilated enclosures to take advantage of natural lighting and ventilation, the use of light tones on external walls for cooler temperatures and shading of surfaces with greater exposure to the sun. Thus, despite originating from a centralising measure, the production was infused with local architectural identity.

5. FLEXIBLE SCHOOLS' DESIGN

The schools were distributed in six of the nine municipalities that made up the Metropolitan Region of Recife during that period. The greatest concentration of new school facilities occurred in the southern portion of Recife, in line with the urban expansion policies of the time.

Upon identifying these schools in Claudia Loureiro's doctoral dissertation, we pursued research in the State Education Department archive and discovered others with similar characteristics. We then visited these schools, which are detailed in the table below **(Fig. 2)**.

The first school was the Santos Dumont School, built in 1973 in the Boa Viagem neighbourhood of Recife, which until then was a summer resort area, but, since the mid-1960s, has been permanently occupied. Its design includes units of covered spaces established according to a module and distributed along linear circulations, making the paths more predictable. The circulation areas are configured in a straight, continuous form, within a certain formal rigidity. The school's sectorisation is established in an atypical way, with its administrative sector located peripherally to the blocks and its living spaces distributed on opposite margins. A second school was built on the land, adopting the same modulation and rhythm, continuing the existing mesh and modular coordination.

Another school located nearby is found in Pina, a neighbourhood characterised by its shantytowns. João Bezerra School dates back to 1978 and was designed by architect Anselmo Luiz Campelo, who adopted the classroom as a module and arranged them diagonally, establishing small courtyards between them. The classrooms are distributed in two blocks, accessed through central circulations. The school presents a very simple architectural programme; in addition to the classrooms, it includes a library, administration office, secretary's office, cafeteria, pantry, rooms for medical and dental care, teachers' room, and a centrally located covered hall. The service and administrative sectors are positioned next to the hall. Regarding the flexibility of the project, the potential for multipurpose use through modular coordination and extensibility is evident.

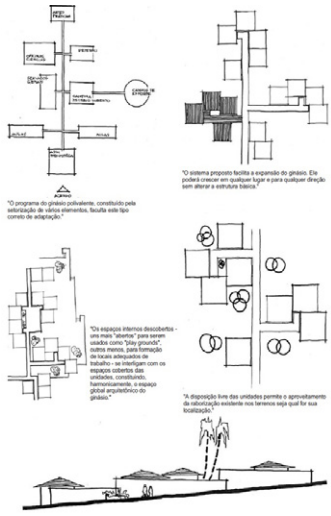
Dom Sebastião Leme School, built in COHAB, a peripheral area of Recife, also shares these characteristics. The author of the project and its year are unknown; however, it bears a strong resemblance to Áurea Cavalcanti School, located in Olinda and designed in 1973 by Anselmo Luiz Campelo. The use of modular units can clearly be seen in the plan. Each of the rooms

7. Armando de Holanda. *Roteiro para construir no Nordeste*. (Recife: Federal University of Pernambuco, 1976).

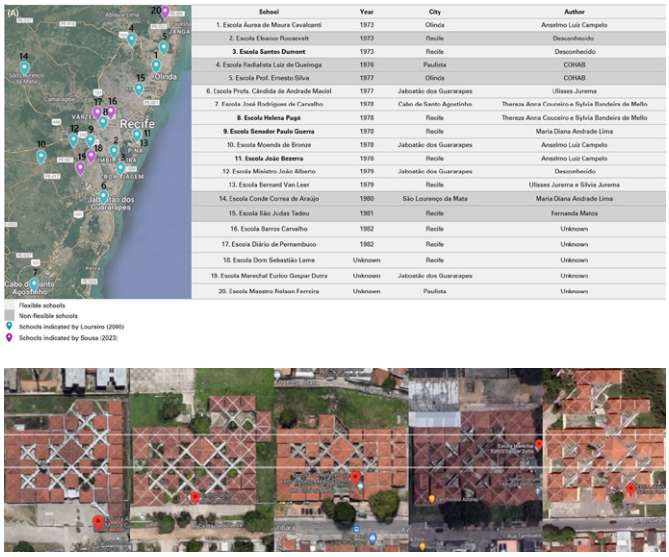
is covered by a four-slope roof, and there is no grouping under a single roof in any of the blocks. This strategy reinforces the idea of the mat building, opening up diverse possibilities for expansion or reduction of the building.

Thus, its form closely resembles the projects associated with the structuralist movement in architecture, featuring alternating independent units and uniformly distributed courtyards. The passages present in these courtyards are arranged diagonally to the rooms, aligning with the large, covered hall at the centre of the ensemble.

The mesh is quite flexible and receptive to any alterations if the modular unity is preserved. There are also gains in multipurpose use as the environments can be freely relocated. The project also provides clearer indications for users about the locations of their environments.



However, this type of project sectorisation may limit the form's freedom. There is a loss of the freedom that extensibility could offer if the sectorisation were less rigid, a context that would allow for more unpredictable construction adaptation. This characteristic is particularly useful in areas of urban expansion, where there is no clear prediction in terms of how the surrounding occupation will occur. Over time, alterations in the environment have restricted the building's growth potential.



This type was identified in schools located in various areas of the Metropolitan Region of Recife, although only one of them is mentioned by Loureiro, the Áurea Cavalcanti School. Figure 3 illustrates this similarity and highlights the positioning of the covered hall, which is uniform in five buildings. Such similarities suggest the existence of an architectural type in this production.

The buildings exhibit specific differences in their formal distributions. However, these differences primarily arise from variations in size and programmatic requirements. Furthermore, they have been situated in distinct urban contexts, which influences openness to modifications.

Another example from this production is Senator Paulo Guerra School, located in Barro, Recife. The building is structured in three blocks: the administrative and technical teaching sector near the entrance, a block that houses laboratories, a hall, and the service sector, and a third of the classrooms. Similarly to other school projects previously presented, the module corresponding to a classroom is used, subdivided into administrative and service sectors and doubled in laboratories. The only element that deviates from this modulation is the covered hall. A main path connects the blocks, and these are again cut longitudinally in centralised circulations, although there are external circulations. This layout allows the building to grow both in the direction of the main path and by expanding the existing blocks at the ends.

Located in San Martin, a working-class neighbourhood in the western area of Recife, the Helena Pugó School was designed by Thereza Couceiro and Sylvia Bandeira de Mello. Unlike other schools, it uses a small scale and groups its spaces into well-defined quadrangular modules, rather than treating each classroom as a modular unit.

Its pedagogical sector comprises classrooms, laboratories, physical education facilities, locker rooms, a typing room, spaces for practices, a library, and a hall. This school presents the greatest potential for extensibility among all the schools studied here, as its layout, with circulation through enclosed environments, allowing it to expand in all directions through associations in the mesh.

In terms of disadvantages, the layout of the blocks follows an extremely functionalist mould. The school environments are limited to the built area, without a connecting element between its blocks, leaving the external area for residual use. With time, the school expanded its circulation to accommodate annexes.

In general, the Department of Education has rarely modified the schools to accommodate new uses, and potential for expansion was seldom made use of. Figure 4 demonstrates how some schools accommodated new spaces in their meshes. Comparisons were made between original designs and the current situation, verified through site visits, aerial views, and files provided by the Department of Education.

The continuity of the spatial logic established in the project by the insertion of new elements in the design is notable. This logic is presented with greater intensity in the schools more aligned with the concept of mat-building. The sample seems to indicate a greater propensity for interpreting school equipment as an element open to alterations in cases where the module and mesh are stronger in the architectural design.

However, the schools have seen few additions to their initial structures, possibly due to limitations imposed by the urban context of expanding neighbourhoods and as a result of political-administrative reasons. In this production, the incompatibility between the project and its use led to a progressive degradation of the school buildings. Vandalism and insecurity in these neighbourhoods, eliminating permeability to the outside, led to the implementation of walls and grilles, and further contributed to this degradation.[8]

6. CONCLUSION

Mat-buildings possess architectural attributes that can be well assimilated by the demands of contemporary education. They easily accommodate changes or expansions in requirements and maintain visual unity despite a de-hierarchized form. The adaptations made by MM Roberto for a school type for impoverished northeastern zones, combined these attributes by detaching it from the rigidity of a pre-established structural mesh. However, new urban challenges over recent decades have imposed limitations on the type, highlighting the need to search for responsive adaptations to the particularities of the 21st century.

Investigations specifically aimed at flexibility in school architecture are scarce. However, it is essential to delve into the topic to tackle the problem of obsolescence in public schools, particularly prevalent in communities with greater socioeconomic vulnerability. ■

BIOGRAPHY

Larissa Leão Silva de Sousa is an architect who graduated from the Federal University of Pernambuco (UFPE) in 2021. She is currently a doctoral candidate in urban development at the Federal University of Pernambuco (PPGDU-UFPE). She holds a master's degree in architecture from the Postgraduate Programme in Architecture and Urbanism at the Federal University of Minas Gerais (NPGAU-UFMG), under the research line Theory and History of Architecture and Urbanism and its relations with other arts and sciences.

Fernando Diniz Moreira is an Architect (UFPE, Brazil, 1990) and historian (Catholic University of Pernambuco, 1991) with a PhD in Architecture (University of Pennsylvania, 2004). He is a Full Professor at the Federal University of Pernambuco (UFPE) in Brazil, where he has been teaching since 1996. He was the coordinator of Brazilian Docomomo (2016-2017) and twice elected Federal Counsellor at the Brazilian Council of Architecture (2011-2017). His professional experience also included conservation plans for urban districts, convents, and other listed buildings.

THE GASOMETER IN VIENNA

MARKUS TOMASELLI
TU WIEN

ABSTRACT.

The four "gasometers" from 1899, which have been listed buildings since 1978 and were once among the largest gas production facilities in Europe, were extensively revitalised between 1999 and 2001. The architects Jean Nouvel, Coop Himmelb(l)au, Manfred Wehdorn and Wilhelm Holzbauer and their teams each redesigned one of the four cylinders and created a modern, mixed-use district in Vienna by converting these industrial monuments while retaining the old outer shell.

The lighting of Vienna's Ringstrasse increased the demand for gas, leading to the decision to build Europe's largest gasworks at the time. Construction work on all four tanks have been completed in mid-1898 and they were ready for operation on 17 July 1899. After the shutdown in 1986, the tank bells were dismantled and removed, leaving behind the domes, decorated with brick walls. At the beginning of the 1990s, the empty Gasometer D was used for clubbing. From 1999 to 2001, 615 flats, 230 student flats, 11,000 m^2 of office space, an event hall for 4,200 visitors, the state archives and a shopping centre with an original 22,000 m^2 of retail space were built in the shell structures. The article shows how this transformation process has been embedded in the city's urban transformation strategy as part of the European Union's Urbion funding program. It also shows the underlying discussion of the architectural possibilities for intervention in terms of the changes of use of this industrial monument.

1. INTRODUCTION

In the late 19th century, Simmering was a busy industrial center with factories, warehouses and production facilities. The gasometer complex, which consists of four massive cylindrical buildings, was originally built between 1896 and 1899 to store gas for Vienna's lighting and heating. Designed by the architects Friedrich von Schmidt, Wilhelm Aicher and Karl Heifer, the gasometers quickly became symbols of Vienna's industrial efficiency and technical progress. After 1986, the four large cylinders fell into disuse, caused by the switch to natural gas for Vienna's gas supply. In the 1990s a new use for the listed buildings was considered. In 1999 - one hundred years after their completion - the conversion into a modern residential and commercial center started, easily accessible from Vienna city center and St. Stephen's Cathedral in just 8 minutes by the U3 underground line. The gasometers are occupying 220,000 m2 and stand as an independent city within the city. The high level of identification of the approximately 1,500 residents with their living space has led to the formation of a large residential community, which exists both, virtually and in reality, as an association and active neighbourhood community. Numerous theses and dissertations in the fields of psychology, spatial planning, architecture as well as articles have been written about this project.

2. SOFT URBAN RENEWAL IN VIENNA

In Vienna, housing subsidies are used for the refurbishment of "Gründerzeit" buildings as part of the "Sanfte Wiener Stadterneuerung "(Gentle Viennese Urban Renewal), an UN-awarded subsidy program for the refurbishment of historic city districts. The rents in such subsidized renovated residential buildings serve exclusively to refinance the renovation costs for a number of years. This approach has made it possible to upgrade many "Gründerzeit" neighborhoods without displacing the resident population. "Soft" urban regeneration projects in Vienna represent a holistic approach to revitalizing neighborhoods through community-based initiatives, social interventions and cultural programs. In contrast to traditional urban regeneration measures, which focus primarily on physical infrastructure and redevelopment, soft urban regeneration emphasizes social cohesion, community involvement and improving the quality of life.

Vienna is renowned for its high quality of life and progressive urban policies. It has long been committed to promoting inclusive and sustainable communities. The realization that vibrant, livable neighborhoods are not just about buildings and infrastructure led to the emergence of soft urban regeneration projects. These projects demonstrate that the people who live in a neighborhood are the most important factor in determining its success. Vienna's soft urban renewal initiatives are not just about preserving and improving the historic building fabric. They also tackle social challenges that can arise from redevelopment measures (social segregation), promote cultural diversity and maintain social integration of residents in their neighborhood's high number of affordable housing units in Vienna is generally viewed positively, but the high-income limits for eligibility for these units are often

criticized. The trade-off between social targeting and social mix undoubtedly exists in Vienna as well, but the frequent demand to open up social housing exclusively to very low-income households make social mixing impossible and causes social segregation in the city Vienna, the policy of social inclusion has so far succeeded in largely avoiding subsidized housing with social problems. In the context of context of upgrading the historic city, the EU-funded URBION I project of the City of Vienna at the end of the 1990s provided a significant impetus for improvements to the urban structure of the "Gürtel". The success of these interventions led to the city's subsequent application for the Urbion II project for the" Erdberger Mais".

3. URBION II

On 28 April 2000, the European Commission decided to launch a community initiative for the economic and social regeneration of urban areas. This decision is based on Article 20 of Council Regulation (EC) No 1260/1999 of 21 June 1999. The Vienna URBAN II area, with a total of around 160 hectares and almost 22,800 inhabitants, is located in the south-east of Vienna. It consists of parts of the 3rd and 11th districts of Vienna; the centre is the so-called "Erdberger Mais". The area is located in the south of Vienna on one of the busiest roads in Europe. It comprises parts of the 3rd and parts of the 11th district of Vienna. The majority of residents lived in the western part of the area, which also had a partially outdated building fabric. The rest of the area was dominated by commercial use. In the years 2001 to 2006, this programme was intended to facilitate sustainable improvements for this area and its inhabitants. In order to ensure that the gasometer transformation project is integrated into a neighbourhood worth living in, an administrative and economic policy initiative was launched with the support of the European union for the transformation of the surrounding industrial area with the Urbion II project.

4. GASOMETER

The Gasometer housing project serves as a testament to the innovative spirit of adaptive reuse and sustainable design. Led by well-known architectural firms such as Jean Nouvel and Coop Himmelb(l)au, the redevelopment of the Gasometer complex involved a careful balance between preserving the historic integrity of the structures and introducing contemporary design elements. One of the most striking architectural features of the Gasometer housing project is its seamless integration of old and new. The framework of the cylindrical tanks, which are both rugged and beautiful, have been preserved. This serves as a reminder of the site's industrial past. At the same time, modern materials, finishes, and amenities have been introduced. These enhancements serve to enhance functionality, aesthetics, and comfort.

Despite the involvement of four Architects, only two development strategies were possible for the Gasometers, the ring and the centre-in variants. The challenge of designing a circular building lies in the difficulty of directing light. The architects Jean Nouvel, Coop Himmelb(l)au and Manfred Wehdorn opted for a circular structure. They constructed a residential and

office ring of up to eleven storeys within the cylinder, creating a large circular atrium. The interior of Nouvel's new structure for example has a diameter of 34 metres. In contrast, Wilhelm Holzbauer opted for a centralised approach, constructing a star-shaped structure in the centre of the cylinder. This divides the interior into three spacious gardens and does not touch the gasometer wall. Coop Himmelb(l)au also deviated from the ring development.

4.1 DEMOLITION AND SECURING THE STRUCTURES

The dome covering was dismantled according to a statically specified procedure in order to keep the supporting structure in balance. The pressure ring was supported by a specially constructed platform, which was initially mounted on a crane tower. In order to prevent the segments from buckling downwards during lifting, the individual dome segments were braced with steel cables. In order to be able to lift the entire segments, the wind bracing and the angle profiles were removed in every second segment. Hydraulic presses were used to press the compression ring up from the platform in order to relieve the tension. In order to maintain the balance, once the tension and compression rings had been relieved, the segments were lifted off one after the other in a statically specified sequence using tower cranes with a hook height of between 69 and 82 metres. The lifting was carried out in such a sequence that two opposite segments were always lifted first, followed by those that were 90° rotated to the segments that were dismantled first, and so on. As soon as the segments were dismantled, they were taken apart once in the centre and transported away for reinforcement and refurbishment. In order to realise the gasometer project, numerous openings had to be created in the gasometer walls. This proved soon to be a challenging endeavour. The masonry, in particular in the lower (basin) area, showed the strength of reinforced concrete, necessitating the use of mining equipment. Milling machines were employed to tackle the masonry.

On the one hand, the masonry, which was 5.40 metres thick, was worked on with mining cutters. In the upper area, where the wall thickness was "only" 90 centimetres, it was cut open with diamond-studded steel cables. In order to enable the installation of flats, offices and shops, which require a great deal of light, numerous new openings were cut into the skin of the gasometer. The decision to alter the gasometers, which are listed buildings, has been met with some controversy. However, it is clear that the new purpose necessitates such a change.

4.2 THE NEW GASOMETER, A MULTIFUNCTIONAL PROJECT

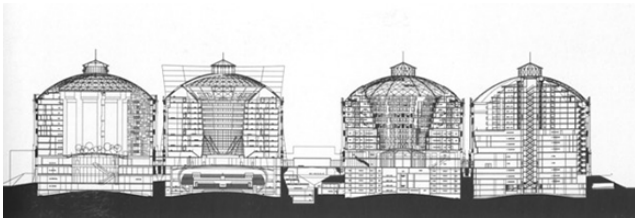
The four-cylinder tower blocks with their flats in Simmering were completed in summer 2001. At that time, the shopping centre in the basement, which had originally approximately 70 shops, opened simultaneously. The Gasometer City, originally known as the "G-Town", was completed, but its urban surroundings were far from it and would not be for a long time. This is where the next phase of transformation commenced with the realisation of the Urbion II project.

One particular challenge for the engineers was the event hall in Gasometer B. It is uncommon for a rock hall to be constructed in a

residential building. Here, however, the experiment was undertaken. The hall is a concrete construction that rests on rubber feet and has no structural connections to the gasometer. In October 1999, the go-ahead was given for the extension to Gasometer B, which was planned by Coop Himmelb(l)au. Underneath the building is the underground car park of Gasometer B (see above), while the building itself is colloquially referred to as "the shield" by local residents. It comprises 116 residential units and offices.

5. THE FOUR CYLINDERS

A – JEAN NOUVEL



French architect Jean Nouvel implemented a shining body in the cylinder, detached from the historic façade and orientated inwards. It was of great importance to him to convey visual lightness through the use of glass and reflective steel, and to create a synergy between the existing outer wall of the gasometer and the new construction. Each of the eleven residential floors contains approximately 20 flats, which are divided into blocks of two. In between, there is open space of approximately one flat in width. The residential floors, which begin at a height of around 25 metres, contain around 120. These Gaps between the individual buildings make the listed gasometer façade with its high windows visible. This, as well as the glass fronts of the flats and the mirrored remaining walls, ensures a high utilisation of sunlight.

Below the flats are three office floors, three shopping centre floors and an underground car park. The underground station adjacent to Gasometer "A" is located directly in front of the main entrance to the shopping centre. There are also offices on the second to fourth floors.

B – COOP HIMMELB(L)AU

The architectural design of the Gasometer B was created by the Viennese architectural firm Coop Himmelb(l)au, Wolf Prix and Helmut Swiczinsky. Its distinctive exterior features an 18-storey residential building with a shield-like extension. The historical cylinder and the extension collectively comprise 254 residential units. The "shield" should symbolise the transformation of the Gasometers into a new form of urban living. If the sign were absent, it would be impossible to discern that a new structure had been erected on the site, was one of the arguments for this addition. The 1,400 m^2 event hall has a capacity of 4,200 people and is of particular importance for Vienna, as there was previously a significant gap between the Wiener Stadthalle, designed by Roland Rainer in the late 50ties with a capacity of up to 16,600 visitors, and the other event venues in Vienna, with a maximum of approximately 1,500 visitors. Furthermore, music groups that were unable to fill the Stadthalle were too expensive for most smaller venues. The flats are arranged in a continuous circle around the perimeter of the gasometer, with a 20-metre diameter light passage in the centre. The windows on each floor of the tower are aligned closely together. But definitely the striking recognisable feature of Gasometer B is the shield-shaped extension leaning against the north. With this project, architect Wolf D. Prix (pictured) from

Figure 3. Coop Himmelb(l)au, Manfred Wehdorn, Wilhelm Holzbauer, Jean Nouvel – Vienna, 2001, https://upload.wikimedia.org/wikipedia/commons/thumb/1/17/Gasometer_wien.jpg/2560px-Gasometer Wien, May 5, 2024, 17:45 Photo/Map: Arne Müseler / arne-mueseler.com / CC-BY-SA-3.0 / https://creativecommons.org/licenses/by-sa/3.0/de/deed.de

Figure 4. Jean Nouvel, Gasometer Tower A, Vienna, 2001, Floor plan apartments. © Christian Matt, 2007

the Coop Himmelb(l)au team wanted not only to add a contemporary touch to the gasometers but also to increase the usable living space of the building. Gasometer B is the most densely built-up building - not in favour of the residents. However, the sound insulation of the concert hall seems to be excellent. This hall in the "basement" of Gasometer B, is mounted on rubber buffers it "floats" and by this prevents structure-borne sound transmission.

C – MANFRED WEHDORN

The Gasometer C, designed by Manfred Wehdorn, is notable for its adherence to traditional Viennese architectural principles, its abundance of greenery, and its suitability for social interaction. A large staircase-shaped courtyard, or atrium, serves as the centrepiece of this Gasometer. Manfred Wehdorn, who was a well-known architect and professor for monument preservation at my university, the TU WIEN composed the 92 flats spread over 6 storeys with a light-coloured façade are stepped back upwards in order to achieve more light on the lower floors. The flats start at a height of around 30 metres above street level, with three floors of office space located between the residential floors and the former shopping centre, today known as the "Music City". "Music City" is a functional concentration of shops, rehearsal rooms and classrooms on the subject of music and was designed by ".Megatabs" (architect Daniel Dora) as a specific re-use of the largely vacant commercial space of the shopping centre. The inner courtyard, under a large glass dome, which allows the former mall below to shine through and provides those areas with daylight. The dome is surrounded by a four-meter-wide strip of greenery on which trees have been planted. The

stepped inner courtyard has terraces and pergolas planted with flowerbeds and trees. Wehdorn wanted to realise the "green" arboretum here. A public car park is located under the central corridor of the former shopping centre.

D – WILHELM HOLZBAUER

Gasometer "D", designed by Wilhelm Holzbauer, is the only gasometer without a central inner courtyard and the only one in which each flat has a small green space or at least a loggia. The residential tower in the centre of the gasometer has the shape of a small central circle, with three rectangular "arms". Between these three equally large "arms" are three equally large green spaces, creating three inner courtyards with gardens 35 metres above the street and with a view over Vienna. This form ensures that people don't look into each other's flats or are all orientated in the same open space. There are also garden flats with fruit trees and a profusion of greenery. The garden offers the opportunity to experience the changing seasons, with the blossoming of the cherry tree in spring, the cherries in summer, the autumnal foliage in autumn, and finally the snow that covers the garden in winter. Below the flats, there are three floors above ground and three floors of storage space for Municipal Department 8, the Vienna City and Provincial Archives. Gasometer D also houses the Vienna City and Provincial Archives, with approximately 35 kilometres of shelves, that ensure the appropriate storage of the valuable documents. The actual residential building is situated on the roof of the Archives. ■

CONCRETE ABSTRACTION

JORGE GAMBINI
DEPAU/IP Y DMP/IT, FADU/UDELAR

ABSTRACT

Bayardo, the architect, and Tizze the structural engineer completed the drawings for the "Urnario Municipal no. 2" (Municipal Ossuary no. 2, as it is known in English) in 1959. The building, erected in 1962, is a massive structure designed to accommodate over 18,000 funerary urns. Its distinctive identity is founded on the gravitational character of the 2,800-tonne exposed concrete structure. and its bare boundaries. The building guides users on a perceptual journey characterised by increasing levels of spatial complexity and formal abstraction.

The ossuary embodies many of the themes influencing 1960s architecture, such as the eloquence of neutral form, bold control of technological means, optical conception of static structure and integration of the arts. Despite being recognised in various international publications and designated as a National Historic Monument in 2014, it lacks a comprehensive framework for maintenance and conservation.

The analyses discussed in the article are part of an extensive multidisciplinary research project conducted[1] in collaboration with the Faculty of Architecture, Design, and Urbanism of the University of the Republic and the Municipality of Montevideo. This project aims to guide future preventive and restorative interventions to ensure the preservation of the Ossuary.

The paper provides a detailed view of the formal analysis of "El Urnario," the design strategies developed by Bayardo, and the key points on its abstract visual construction and physical presence.

> We intended the meaning of the work to be easily perceptible: a severe and austere exterior contrasted with an interior space, like a patio, in which richer and more varied nuances are pursued. Elevated from the natural level of the land so that the surrounding landscape is not interrupted and is offered to the viewer as a series of panoramas limited by the architecture, the volume opens to a square interior patio, which is reached after crossing a porticoed space that seeks to "crush" the observer, due to the play of its dimensions.[2]

1. THRESHOLD

In Bayardo's Ossuary, the observer encounters a particular paradox between the massive and corporeal exterior, marked by constructive realism, and the abstract and extensive interior. Here, the visual arrangement of lines and surfaces, modulated by natural light, surpasses all individual signs of death on which their precise geometry was based.

The mould in which the concrete was cast left traces of its geometric and constructive order on the surface of the facades, leaving testament to the specific conditions of its production and the vicissitudes of the building and its surroundings over time. The unit of measurement is the height of an unplaned formwork board, which ranges from 13.5 cm to 14 cm. In this way, the pillar measures 18 boards in height, the beam-wall 48 boards and the self-supporting wall marking the access, 11 boards.

The gravitational compression exerted by the Urnario's structure on space and the profound shadow it casts configure a transitional space where the body and mind physically recognise the ceremonial nature of the work **(Fig.1)**. Stepping over this threshold implies being transformed by an intimate form of knowledge, which arises from the formal configuration of the architectural space and the intentional precision of the construction details. The threshold is a perceptual device that offers us the image of the park as a panorama transfigured by contrast.

The threshold is conceived as an annular deambulatory, topped by the tombs block that rises 2.40 m above the pavement. The longitudinal marking of 58 boards defines the texture of the slab bottom. At the ceiling, the diagonal meeting of the formwork at the corners of the quadrangular ring ensures that the modular order of the elevations rotates on the exterior edge, reinforcing the perception of continuity and material unity. The encounter between the slab and the façade is marked by a sharp edge, lacking a drip edge, intensifying the monolithic and reductive image of corporeality that we observe on the outside. The detachments that are currently observed in the cement coating of the exterior edge reveal how the Municipal Columbarium project's architectural intention takes precedence over the construction, to the point of affecting the material stability of the work and even denying it

The vertical outer limit of the threshold is defined by the eight trapezoidal screens, which assume the isometry of the square, adopting an identical arrangement in each of the elevations. The screens align with the facades, freeing the corners with a cantilever of 8 m and defining a central

1. This article presents part of a multidisciplinary research project conducted by: Juan José Fontana, Jorge Gambini, Mary Mendez, and Fernando Tomeo.

2. Nelson Bayardo, "Urnario del Cementerio del Norte," *Revista de la Facultad de Arquitectura*, no. 4 (febrero 1963): 8.

portico spanning 20.50 m. This structural configuration means that the perception of the supports is linked to the position of the observer's body and its movement.

Instead of repeating the exterior edge solution, the bottom of the slab meets the patio's interior façade with a wide recessed perimeter drip in the cement surface. This design choice induces a perceptual decomposition of the building's enclosures. It marks the beginning of an increase in visual complexity as we move inward, transitioning from object to system, making the construction detail a factor that intensifies the form.

2. COURTYARD

At La Tourette, the bare wall of the church lacks formal content other than the resplendent brutality of an indifferent and visually hostile construction surface. In contrast, the Urnario project takes an opposite approach: art substitutes faith drawing our full attention in a secular act of charity. in this case, the wall features a gigantic concrete mural designed for contemplation.

Due to its position, size and plasticity, Edwin Studer's mural is the predominant element of the composition of the space. The manner in which it draws your attention is such that it transforms the entire surface of the pavement into a plane of contemplation. The standing body must face the work directly, making the symmetrical nature of the architectural project evident. The mural directly engages the viewer, exhibiting its dual nature as an autonomous art object and as an aesthetic artefact **(Fig.2)**. It reflects its adaptation to the architectural framework in which it is inserted and which, in some way, proves to be revealing.

The east and west elevations are configured as a volumetric and abstract bas-relief, which breaks down the façade into a succession of geometric planes that respond specularly to the project's symmetry.

The abstract garden space embodies a strong communal spirit, but only two seating options offer a retreat from the mural's influence. The first turns its back on the work and is nestled under the stair-ramp, directing its gaze to the north and downwards to a pond of golden proportions inviting us to sink our thoughts into the reflective surface of the water. Positioned along the circulation path that links the patio entrances, this bench becomes a transit and meeting place, offering solace in shared moments. The second bench moves away from the paths and seeks privacy and seclusion. Sheltered by a willow and a raised planter containing collective offerings, this bench faces the screen pillar. Daylight illuminates the pillar, drawing the eye upward and into the deep shadows of the openwork wall.

The patio's boundaries, with their rich and varied nuances, aim to create a therapeutic space. The sensitive use of detail and architectural form seeks to contain the emotional and moving force of the moment.

3. COLUMBARIUM

The stair-ramp ascends towards the funerary ring tangent to the north façade of the patio. This ascent offers a close view of the mural, which reveals

the haptic nature of its components. Its dark, porous concrete is marked by 14 cm vertical formwork boards on the continuous light concrete wall background, which features horizontal formwork boards indicating its architectural significance. The sunlight accentuates the volume of the pieces that make up the work, distinguishing them from the background surface.

The climb towards the raised columbarium occurs perpendicular to the project's axis of symmetry. The concrete abstraction of the columbarium is achieved through a stark disconnection between function and experience. Experience paradoxically denies its symmetrical material corporeality. We are faced with a perceptual construction that transcends the formal law of the project, offering us an abstract and situational aesthetic experience **(Fig.3)**, whose unstable centrality is centred on the subject, their position and movement within a material geography where order is permanently concealed.

The enclosure is emphatically delimited by a wall of urns that defines the funerary space's outer perimeter. It forms an absolute limit, except for the four niche-shaped openings of the north side. While the outer limit is closed and uniform, the limits of the patio are complex and present varying degrees of openness. The free-standing shelves, mezzanine layout and material elements that define the enclosure adhere strictly to the the floor plan's bilateral symmetry, a symmetry that is systematically disrupted by experience. The observer encounters a fluid, continuous space that solely permits extremely close or distant, foreshortened views of the urns, in which the position of the body on the axis of symmetry is systematically prevented by the architecture.

The 20.50 m long wall that supports the stair-ramp defines the conditions of the interior limit of the southern sector, a tubular space with a square section measuring 6 m x 6 m, divided in 2 by a free-standing urn block of 3.30 m. This block extends approximately 3 m towards either side of the mural. Its position in the centre forces an asymmetrical and partial contemplation of space, which contradicts the symmetry and unity of the construction. Three skylights cut across the roof and cast geometric lines of light over the walls of the tombs. The natural lighting setup guides the viewer's progress while reinforcing the dual nature of the funerary space as both a part and a whole. In the east and west sectors, two large openings face the patio, showing an asymmetrical configuration of planes, made up of the perimeter wall of tombs and a free-standing shelf, 2.30 m high and 11.70 m long, extends to the southern block without touching it. The natural lighting coming from the patio highlights the separation of the free-standing blocks and the back wall.

The north wing is cut by a longitudinal mezzanine situated below the midline of the columbarium's height, dramatically compressing the space below. A concrete parapet visually divides the total height into two practically identical parts.

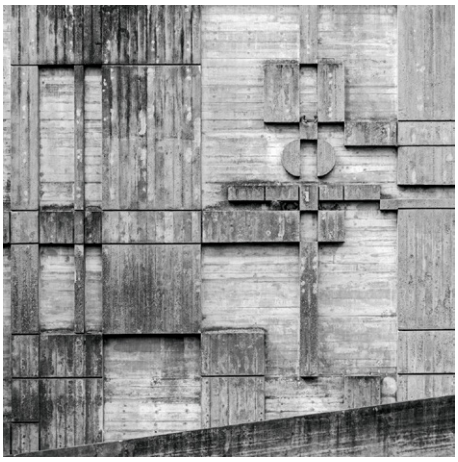
While the continuity of the envelope, the pavement and the slab bottom maintain the spatial and material unity of the funerary ring, the ostensible changes in scale and proportion of the lower level of the northern sector

separate it. In a frontal view of the mezzanine, this crossroads between continuity and fissure becomes evident. Towards the patio, the sturdy concrete parapet folds to form the railing of a cantilevered staircase that advances towards the viewer. The upward and vertical movement corresponds to a horizontal movement in depth, induced by the continuity of the surfaces of the floor and the outer wall of the urns, pushing the body towards the shaded area under the mezzanine.

When beneath the 2.30 m mezzanine, the dominant perception of the funerary space seems to shift from visual to tactile. Compression emphasises the sensation of proximity of the limits of space, giving the observers a sensory experience even without direct contact. The urns' height divides the space into two narrow passages that are as independent as they are different.

A 20 m long panoramic window opens towards the patio, which has been designed to allow for ideal contemplation of the mural. The viewer's distance ensures a complete view of the mural, with the middle height offering an unobstructed perspective. The panoramic opening allows the possibility of visualising the symmetry of the architectural artefact, but only to offer it from its condition as the frame of the work of art.

To the north, under the mezzanine, the space grows darker and in a certain sense, narrow and claustrophobic. This area, which holds the greatest compression and drama of the project, is violently penetrated by a volumetric light in the middle of the path. The opening, located in the centre of the outer limit, reveals the thickness of the funerary wall. Its jambs and sill reflect the light from the north, configuring a luminous parallelepiped that, with its elevated centre of gravity, draws the space upwards and outwards, directing the observer's gaze towards the sharp, dripless edge that marks the limit of the funeral space. Opposite the opening, the four niche-shaped openings frame an idyllic horizon, in which the gaze is lost in the park. The hand relaxes and seeks support from the windowsill, momentarily forgetting what defines the thickness of the wall.



Both passages allow the gaze to recover a position on the axis of the bilateral symmetry of the project, a location that, instead of returning to us the formal and operational logic of the funerary artefact, projects us outside its limits, presenting us with a scene capable of sublimating, equally, both death and architecture.

In the funerary ring, the conditions of perception have been intentionally designed as a visual instrument, privileging the apparent form of the object over its operational form. Any observation that results in a comprehensive view capable of recognising the artefact's typological order and functional design, has been categorically prevented.

The possibility of an affirmative experience is thus left open, which ultimately exposes the autonomy of the subject. In this context, we can borrow the words with which Robin Evans analyses and describes a building as different and as close as the Barcelona Pavilion:

By virtue of its optical properties, and its disembodied physicality, the pavilion always draws us away from awareness of it as a thing and

Figure 4. Nelson Bayardo, Urnario Municipal, Montevideo, Uruguay, 1959-1963, columbarium. (©Leonardo Finotti 2016).

Figure 5. Nelson Bayardo, Urnario Municipal, Montevideo, Uruguay, 1959-1963, Southern sector of the columbarium, with the hidden urns. (Julio Navarro-Carmen Moreno, In "Urnario del Cementerio del Norte," *Revista de la Facultad de Arquitectura*, no. 4 (1963): 16).

draws us toward awareness of the form as we see it. Sensation, forced to the foreground, pushes consciousness toward apperception. The pavilion is a perfect vehicle for what Kant calls aesthetic judgment, where awareness of our own perception dominates all other forms of interest and intelligence.

But, Kant insists, outside of their seemingly meaningless activity, we make our own destiny.[3]

4. THE NEGATIVE PATH

There are several plans of the building that highlight the determining role of the funerary shelf as the basis of the organisation, structure and form of the building. The ground and first floor plans reveal a symmetrical and regular arrangement of shelves in the funerary area. The "PN° 5" plan relates the position of the openings on the north façade exclusively to the distribution of the standard module that houses the ballot boxes. "PN° 5a" shows how the structural reinforcements of the disc beams in the funerary ring coordinate with the position of the slabs and screens of the shelves.

On the shelves, the naked urns confront viewers with a kind of operational transparency, in which the device ostensibly exhibits its character as a funerary machine. stacked and multiplied to an overwhelming number, immerses the observer in a sense of infinity, akin to Kant's "mathematical sublime." It presents an order of such magnitude that it seems to defy the imagination, pushing reason towards the absolute.[4]

In a diametrically opposite sense, contemplation of the meagre proportions of the individual urn prompts us to fill the narrow limits of its inner emptiness with something concrete, with an image or a concept. The urns' fronts feature small acrylic plates that identify the bodies in the abstract and orthogonal matrix of the tomb **(Fig.4)**. Each name creates a specific place for remembrance, making it possible for the memory to be embodied in the offering. Colourful plastic flowers and blurred photographs consecrate the places where, at some point, memory has been transfigured into present emotions.

A series of graphics illustrate the fibre cement plates that cover the ballot boxes, and the uprights responsible for securing them in position determine the apparent order of the form. The flat pieces of fibre cement not only block direct views of the urns but also impose an alternative rhythm and proportions that completely blur the mortuary order of the columbarium.

The project highlights a recurring contrast between function and experience. It prevents any insight into the operational condition of the modular matrix, which remains hidden in the background while maintaining the efficiency of the funerary device. Historical photos document the Municipal Ossuary with its closed shelves **(Fig.5)**. These images depict the funerary ring as an autonomous plastic reality, which, based on its visual configuration and its vague materiality, obscures its inherent function as an apparatus. This radical denial reshapes our perception of the building and the bodies within, reducing them to mere objects. ■

RESEARCHING, DISMANTLING, REBUILDING: THE WORK OF EMILIO DUHART REVEALED BY INTERVENING ON THE HERMAN HOUSE

LORETO LYON

ALEJANDRO BEALS
BEALS LYON ARQUITECTOS

ABSTRACT

This text presents some findings during the task of researching on, dismantling and restoring a single-family house designed by Emilio Duhart during the early sixties in Chile. By examining archive material, we traced back and tried to understand the project development and leading concepts by analyzing Duhart's other contemporary projects; not only to verify the recurrence of certain concepts and ideas within his body of work but also, to explore the different strategies used to materialize them.

However, it was the process of physically dismantling everything that was damaged in the house -almost everything besides the concrete structure- what really allowed us to reveal the main architectural principles behind the whole design process. A silent dialogue both with architects already gone and the house itself, which provides the guidelines to renovate the house, but also to reflect on some of our own design principles when making architecture.

1. THE DISCOVERY

For many years we walked past this enigmatic structure, trying to guess how the interior and the garden looked like, all hidden by a high wall that kept everything secret. Seen from the street, it only appeared as an exposed concrete skeleton overrun and consumed by a mantle of ravenous creepers, which already seemed to have devoured the softer parts. Not much else could be seen under the bush, but the detached volume of a triple height staircase poking on a corner, surrounded by beams and wrapped in a thin tissue of timber and frosted glass. Through this veil, it was possible to see the blurry shadows of ivy already spreading in, moss and droplets running down the glass, also colonizing the blackened concrete surfaces. At dust, a soft and green glow came from within, and just a few times, a fading human outline moving up or down inside this frosted box, looking like the distorted figure descending a staircase in Duchamp's painting.

It was when we first visited the Herman House (1966) that we realized it was designed by Emilio Duhart (1917-2006), an architect known mostly because of his remarkable public buildings created at the time of the pinnacle of the modern movement. This is one of the few houses he designed which still stand, and of which we were unaware of its existence, since not a drawing or a picture of this house has ever been published before. It is also, perhaps, the only house where the architect addressed similar concepts and strategies to those used in larger public projects, like the free plan and the free façade.

2. THE ARCHIVE

The Herman House is in a neighborhood developed in the 1950's at the foothills of Cerro San Cristobal, Santiago's metropolitan park. At the time of its construction, this area was on the outskirts of the city, now absorbed by its growth and therefore much more central. Despite of changes in the context, and because of its location close to the hills, somehow the feeling of being on a fringe of Santiago remains.

Once we realized this house was designed by Emilio Duhart, we began to research to know more about its history and define a point of departure for future transformations. Fortunately, all the drawings of the project were at Universidad Católica's documentation center, keeper of Duhart's archive. However, and together with this 'informed methodology', we also wanted to explore a more experiential approach; to think on future transformations by continuously visiting, dismantling and intervening the house.

The drawings of the Herman House cover a span of three years, from 1963 to 1966. Despite being a single-family house, the design process took a relatively long time, and as expected in a time lapse like this, different young architects and draftsmen intervened. Borja Huidobro (later to become Duhart's son in law) and Christian de Groote amongst them, two of the most prominent architects in the history of Chilean architecture.

Even though the house underwent several changes and transformations along the whole process, what we find to be the most prominent aspects, and which are also recognizable in other keystone projects of Duhart, remained: a

strong connection and appraisal of the surrounding geography and landscape; the pursue of flexibility to allow for change and transformation; the presence of vegetation and continuity with nature; and attention to detail in the relationship between architecture, the human body and the experience of space.

3. DESIGN STAGES AND CONCEPTS

We identified four main moments during the design process of the Herman House: a schematic design, design development, construction documents and lastly, a landscape design.

3.1 SCHEMATIC DESIGN: THE VALUE OF LANDSCAPE AND GEOGRAPHY

Duhart had a strong connection and appraisal of Chile's landscape and its geography, which he tried to value and incorporate into his projects. In the plan drawings, for example, there was often an icon indicating, besides the four cardinal points, the main mountains surrounding the valley of Santiago. Therefore, the plans are not only referred and organized according to the movement of the sun, but also to the main geographical events in the valley (Montealegre, 1994). The first plans and elevations of the house already define the position of the volume, closer to the street and leaving exactly half of the lot empty. The decision of freeing a big backyard to the west, probably linked to the presence and views of nearby San Cristobal hill and the possibility of creating a continuous and -in appearance at least- more extensive landscape. **(Fig. 1)**.

The house itself is organized within a compact two-story high rectangular volume, surrounded by a perimeter wall that runs around the whole limit of the plot. On top of this volume, a roof terrace, with some curved walls that keep the space closed towards the street and open to the main views of the nearby hill. A dispositive to connect with the geography of the Andes, which remind us of similar solutions used on the roof terrace of the Ville Savoye, the elevated terrace at the Villa Shodhan, or the older sail shaped wall at Casa Malaparte.

At the same time Duhart designed this house, he also worked on the Cepal building. Obviously, the two are completely different in terms of scale and program, however, it is possible to recognize in this smaller structure several concepts already present at Cepal, like the reference to geographical elements and the flexibility that a plan freed from structure allows.

If in the house he creates a connection with the surrounding geography by means of a roof terrace and the views toward both close and distant mountains, his sensibility towards landscape is best appreciated at the Cepal building[1]. Duhart describes Cepal as a building with a double condition: one which can stablish a dialogue with the big geography because of its monumentality, but which also incorporates a smaller and more domestic scale (Auca, 1966)

3.2 DESIGN DEVELOPMENT: FLEXIBILITY AND ADAPTATION

During the first stage of design of the Herman House the two floors are symmetrically divided on its longer axis by a main wall, with secondary load bearing walls both perpendicular to it and along the perimeter.

1. Fernando Pérez, "Emilio Duhart y el Edificio Naciones Unidas en Santiago," en Jeannette Plaut y Marcelo Sarovic, *Cepal 1962-1966: United Nations Building, Emilio Duhart Arquitecto* (Santiago, Chile: Constructo, 2012).

On a second stage, by the end of 1963 and already under the supervision of Christian de Groote, the structure mutates, and the materiality becomes more specific. All in search for an open plan that allows for higher flexibility and future transformations.

The supporting walls on the perimeter disappear and are replaced by a series of concrete columns: three on each of the longer sides and one coinciding with the central axis on the east and west elevations. The main wall that longitudinally divides the plan and a couple of perpendicular walls on the 'service side' of the house, remain.

The result is that now one half of the house becomes a free plan without any structural partition. On the most open side of the plan, the project specifies different solutions to break down the big, elongated space into smaller rooms or situations, always allowing for these partitions to be removed or transformed. At ground floor the aim seems to get the longer site views possible, connecting the front with the back garden, from wall to wall, through the interior of the house. The main space is divided in dining-room, living-room and studio using two accordion screens (modern fold), and therefore, without compromising the continuity of space.

On the second floor the division of rooms is done by sliding doors or very thin partitions. The plan even indicates multiple possible positions for them, reinforcing the idea that these could be changed later in the history of the house and thus, adapted to the will and needs of their inhabitants. We confirmed this when we took down these partitions when renovating the house and found out these were made of very thin timber frames, secured at their base using just some wood wedges against a continuous floor finished in terracotta tiles. **(Fig. 2)**.

The exo-structure set the facades free of their structural constraint, allowing for a greater variety of openings. At ground floor there are narrow and frame-less windows against the concrete slab, big windows in the center framed by thin concrete walls and columns, and long horizontal windows at the bottom. A series of bow windows allow to be closer to the garden, or rather, in the garden. When there is need for an opaque wall, these frames are filled with bricks, and therefore making evident that this border, which never touches the slab, does not perform a structural function. Differently, the outer walls on the upper floor are completely made from timber, but like the ones below, they also leave a full-length horizontal separation before reaching the slab.

If the Herman House is thought as structures to be filled, lived, enjoyed and eventually transformed, the same happens at the Foro Endesa Building (1962), but on a much bigger scale.

The building was commissioned by the National Enterprise for Electricity, to concentrate all their offices in one single building. Emilio Duhart worked in this project together with other two architects: Luis Larragubiel and Gastón Etcheverry. All of them were asked to prepare different schematic designs, and the design proposed by Duhart was the one chosen to be built, not without some resistance from the others[2].

The structure was conceived as what nowadays is a standard for office building typology: a core that contains the vertical circulations and services,

2. Alberto Montealegre, *Emilio Duhart Arquitecto* (Santiago, Chile: Ediciones ARQ, 1994).

and a free plan around it. However, at the time of the design, these concepts were a novelty. From the outside, what gives shape to the building is again an exo-structure: a grid of columns and beams of reinforced concrete which bear the loads on the perimeter, and thus liberates the space between the core and the façade from any additional structural elements. Therefore, the free plans can be divided and adapted at the occupants will. This approach is not only structural and functional, but also constructive. A diagram that explains the building sequence depicts the massive central core being built using a system of sliding formwork, on top of which the construction cranes are later installed. After that, begins the construction of the perimetral frame, and finally the assembly of prefabricated beams and slabs.

In both projects analyzed here, house and tower, flexibility, change and adaptation are sought, even encouraged, avoiding the definitive. Architecture is devised as a backdrop for daily life to happen.

3.3 CONSTRUCTION DOCUMENTS: ON MATERIALITY

During the last stage of the project of the Herman House the biggest exterior transformation happens on the roof. First, a low, pitched timber roof covers the higher slab, but the stairs still arrive to this now inaccessible space. Evidence perhaps that this structure was expected to be removed, if needed to. Lastly, there is an alternative of using the roof terrace simply as an elevated garden: a wooden deck with planters around, which could also be later transformed into an indoor playroom. It is also in this stage, where most drawings of details are dated. There is a particular aspect that draws attention, not only because of the precision of some drawings, but also because of the contrast between the bare concrete structure and other surfaces within reach of the occupants of the house. Handrails within the staircase, flat boards on top of the bow windows and on their backrests. Every element that may meet the body seems to have been designed and built in wood. **(Fig. 3)**.

Besides the timber studs that structure the perimeter wooden walls of the second floor, the handrails in the staircase are the only pieces of timber in the whole house that we could salvaged. Everything else was rotten, cracked, or eaten by insects. The profile of these elements is also the only sinuous shape in the house: an extruded profile that perfectly replicates the movement of a hand sliding over the timber.

The traditional wooden construction, the use of local stone on floors and some walls, together with all the other elements in the space, anchor the building and its spaces to the history and tradition of the place. All evidence of Duhart's permanent will to reference local historical tradition, and to represent it in contemporary terms[3]

3.4 LANDSCAPING: ON CONTINUITY

The last two drawings of the Herman House, dated in 1966, belong to the landscaping proposal. The earlier one is signed by Duhart, a conceptual general planning of the garden, and the latest, by a landscape designer, María Santa Cruz, which mostly indicates the vegetal species following Duhart's

Figure 3. E. Duhart, Beals Lyon Arquitectos. Herman House, Santiago, Chile, 2023. Original wood handrails within the staircase. Credits: Roland Halbe, 2023

design, which suffered little change. The most notorious elements are a continuous shaded border, completely covering the perimeter walls, and a swimming pool, strategically placed along the same view axis of the main living area at ground floor. These two elements contrast with the rest of a rather pale drawing. Additional vegetation and trees are planted in front of the main windows, and nothing obscures the staircase core. The contrast between the perimeter and the rest of the drawing transforms the whole plot into a new, exterior walled room. Thanks to the structural solution that frees the facades from a load bearing condition, it is possible to have big glass planes and apparently floating slabs. Thus, the interior views extend without obstruction to reach this new exterior green boundary, and in return, the natural light and the greenery floods in multiple ways towards the interior of the house.

4. DISMANTLING AND REBUILDING

The original owner of the house, Mr. Herman, lived there for about fifteen years, and then sold it to a younger family, which inhabited it intensely for almost four decades. There was no doubt about it. Door frames with children growing marks carved full height on them, red floor-wax stains climbing on the concrete walls everywhere, a derelict but reckless garden which was already devouring the house, and an old couple left alone living here, with joyful memories, but already too tired to keep going with the house. When we found the house, it was already unattended for too long.

Covered in ivy, the depth of the real damage of the concrete structure and wood elements was hidden, as the precariousness of some constructive solutions: every angle of the columns, beams and walls, was about to fall because of rebar corrosion; rotten timber window frames and secondary structure damaged by insects and fungi; parched wood facades with plenty of grooves; broken glasses; cracked waterproofing; torn vapour barriers and almost no insulation. The installations, never updated, were useless and beyond repair. Despite all this, and having resisted several major earthquakes, there wasn't serious structural damage, but it was urgent to take care of the house to prevent further damage.

Confronted with this unexpected scenario, and to adapt the spaces to our own requirements, we progressively began dismantling all that was damaged or faulty. In the end, we had no alternative but to leave anything but the concrete structure.

As we progressed with this initially unintended process of deconstruction (or 'undoing' the construction), more and more pathologies or constructive deficiencies were revealed. However, not everything was negative, as this turned out to be a fertile process for discovery and reflection. A creative method born out of the violent process of deconstruction. This way we choose not only to base our design choices in old drawings, but mostly, on what the house itself suggested. It was then when we could focus on the qualities and atmospheres we discovered and enjoy.

Probably, every architect has been in the position to imagine changes or corrections when visiting a work of architecture. At least, it is something we

cannot avoid. And we enjoy it a lot: 'that window could be a little to the left, that way you could see that hill from this chair'… 'this floor could have been the same than outside, so you could perceive it as a single space'… 'a pivotal door here would allow for a continuous wall between inside and outside'… and so on. Small adjustments both to enhance what we found has value and to improve what we consider to be shortcomings. A process we frequently use as architects, where whether by visiting or reflecting on a work done by others, then we start creating our own.

If the survey of archive material allowed us to understand the evolution of the project of the *Herman House* and the successive contributions of Duhart's younger collaborators, it was the process of dismantling everything that was damaged or needed to be renovated, what really revealed the main spatial concepts and pursues of the project. This method set the guidelines to adjust or reshape what we consider to be shortcomings, but most importantly, to retain and intensify the qualities that define the identity of this house. An ongoing process of observation and discovery in what will be just another chapter in the story of this house. And probably, not the last one either. ■

BIOGRAPHY

Loreto Lyon (Chile, 1979) received the title of architect from UC (Chile) in 2005. In 2011 she received a Master of Science degree (MSc) in "Environmental Design and Engineering" from the Bartlett, University College of London (UCL).

Alejandro Beals (Chile, 1976) received the title of architect from UC (Chile) in 2001. In 2012 he received a Master of Philosophy degree at the Royal College of Art (RCA), London, where he researched on boundaries and borders in architecture, under the supervision of professor Nigel Coates.

They have taught studios at Cornell University AAP, the IUAV in Venice, Scola da Cidade in Sao Paulo, and Universidad Católica de Perú. Currently they teach at Universidad San Sebastián and Pontificia Universidad Católica of Chile. They have published and exhibited extensively. In 2016 Ediciones ARQ published the monograph Beals Lyon Arquitectos: Public Voids, featuring a selection of works about public architecture. The practice has been recognized with various design awards, like Archdaily's 2020 Building of the Year Award and Oscar Niemeyer Price for Latin American Architecture.

EDUCATING MODERN CHILDREN: LOCAL SOLUTIONS AND STANDARDIZED CONSTRUCTION IN MEXICO

LOUISE NOELLE GRAS GAS
UNIVERSIDAD NACIONAL AUTÓNOMA DE MÉXICO

CATHERINE R. ETTINGER
UNIVERSIDAD MICHOACANA DE SAN NICOLÁS DE HIDALGO

ABSTRACT

At the end of the 1950's, the Mexican federal government began implementing a vast program to build schoolhouses in rural towns and villages all over the country. The program relied on a design that used lightweight prefabricated and standardized elements that could be easily transported and assembled by local inhabitants. The school "kit" also included furniture and didactic materials. The school design was lauded and won the Triennale in Milan in 1960 and was emulated in other Latin American countries. This paper seeks to place the standardized design in the context of rural schools before it appeared through the examination of a federal program carried out in a remote area in Western Mexico: the Tepalcatepec basin. In the 1950s the region was developed through a broad program that built infrastructure, provided electricity and running water, and established hospital and over 200 rural schools. The comparison of the architectural solutions of the standardized schools and those from the preceding program allow for a balanced consideration of both program.

1. INTRODUCTION

Conditions in Europe at the end of the World War I favored the development of modern architecture as did similar situations in other parts of the world. At the same time, social circumstances implied a greater commitment of the State to the growing demand for equal access to housing, health, and education. In response to the demand for education, new paradigms appeared in school architecture all around the world. It is important to note that the architectural solutions for educational institutions varied enormously in response, not only to climate, culture, and region, but also to pedagogical models. The influence of local circumstances became enmeshed with new pedagogies (under the influence of Piaget, Froebel, Montessori, and others) while health issues —specifically the aftermath of the influenza epidemic of 1918 and the constant threat of the tuberculosis— also motivated innovation in school design, as did the increasing participation of women in the work force, particularly as teachers.

Experimentation led to the development of open-air schools in many parts of the world. Richard Neutra's proposals for California and for Puerto Rico, and Jan Duiker in the Netherlands; the rational designs of Juan O'Gorman for economizing school construction in Mexico; the rural schools designed by Luis Nunes in Brazil and Hannes Meyer in Switzerland, in contrast with proposals by Otto Haesler in Germany or W.M. Dudok in the Netherlands, are but a few examples of innovative approaches to school design.

Solutions given to the design of schools in different situations and parts of the world, vary from the interaction of local thinkers or circumstances to the plastic expression of modern architecture, taking into account the materiality and the technology. Sometimes, new pedagogies that stress programs and organization are present in consolidated urban centers. I rural context, pedagogical proposals may vary, and housing has to be taken into account. Furthermore, in rural context, the weight of tradition and vernacular architecture is evident, opposing the prefabrication that seeks to solve the demand, in an expeditious and efficient way. Therefore, it is necessary to analyze both proposals in the light of local conditions, both socioeconomic and environmental.

2. MEXICAN PROPOSALS BY MID 20TH CENTURY

For Mexico, the construction of school became a priority at the end of the Mexican Revolution (1910-1920). During the twenties and thirties, the Ministry of Education built numerous elementary schools primarily in urban areas, many of them with large campuses that included libraries, theaters, and extensive sports installations. Schools in rural areas materialized at the end of the forties, with much simpler programs.

In 1944 the Comité Administrador del Programa Federal de Construcción de Escuelas (CAPFCE) was formed under Jaime Torres Bodet, Secretary of Public Education. From 1944 to 1946 José Villagrán García was executive director of the Projects and Technical Planning Commission and he worked closely with José Luis Cuevas, Mario Pani y Enrique Yáñez. CAPFCE

functioned with a structure that assigned regional coordinators (Jefes de Zona). The early ones included Domingo García Ramos for Campeche, Carlos Leduc for Colima, Raúl Cacho for Mexico City, Juan Segura for Sinaloa, Pedro Ramírez Vázquez for Tabasco, and Luis Guillermo Rivadeneyra for Veracruz.

CAPFCE established federal guidelines for the building of school and, with the regional coordinators, studied the specific conditions and needs in different parts of the country. In the early years schools were built primarily in urban neighborhoods. Rural areas remained largely unattended by the organism until the end of the 1950s with the design of the standardized "aula rural" or rural schoolhouse under Pedro Ramírez Vazquez's leadership at the CAPFCE.

The construction of rural schools in Mexico emerges before the design of the schoolhouse, in a marginalized region in Mexico in the period prior to the "aula rural". The example illustrates the way in which local communities, in coordination with municipal, state and federal government solved their need for schools. It i a precedent for the analysis the "aula rural" and allows for a comparison of the solution with attention to four aspects: the role of local communities in the design and construction of rural schools, the placement and hierarchy of the schools in the settlements, the communal function of rural schools, and their adaptations to climate.

3. RURAL SCHOOL ARCHITECTURE IN THE HOTLANDS OF MICHOACÁN (1947-1958)

In 1947, at the suggestion of the former president Lázaro Cárdenas del Río, President Miguel Alemán established the Tepalcatepec Commission (modeled on the Tennessee Valley Authority) to promote the development of the hot lands in Michoacán in Western Mexico through the construction of infrastructure (roads, airstrips, dams, and irrigation works), the provision of running water and electricity and the construction of schools and hospitals. It functioned under the Ministry of Hydraulic Resources and had ample jurisdiction to coordinate activities between different levels of government (municipal, state and federal) and federal ministries (Health, Education, Agriculture, etc.).

Between 1947 and 1958 the Commission built 206 rural elementary schools, seven secondary schools and four technical schools (forestry, agriculture and a normal school for teachers).[1] During the period from 1947 to 1958, with Lázaro Cárdenas in charge, schools were erected in the municipalities of Apatzingán, Buenavista, Múgica, Felipe Carrillo Puerto and Parácuaro. Visits to the region and the revision of archival materials and historical photographs allow for an understanding of the design of schools and the situation of rural schools previous to the implementation the rural schoolhouse on the part of CAPFCE.

Many of the schools included in the Commission's report existed before the 1940s. They had been built by local communities but were first included in the federal registry in the 1940s when the Ministry of Public Education did a census. This explains the variety in solutions as well as the large number of one or two-room schools with no bathrooms, electricity or running water. Even after the schools were registered by the federal

Inauguración de la primera etapa* (Uruapan: Comisión del Tepalcatepec, 1952), s.p. and Secretaría de Recursos Hidráulicos, *La Comisión del Tepalcatepec. Memorias de los trabajos realizados 1947-1961* (Uruapan: Comisión del Tepalcatepec, 1961).

government, local communities were expected to continue providing funds both for teachers' salaries and for maintenance and repairs.[2]

Other schools that were built with assistance from the Commission received funds from local organizations. For example, the citrus growers contributed funds for a school in Apatzingán and the local soccer league for a school in Caltzontzin. Schools established by the Commission usually had financing both from federal and state government.

The schools built by the Commission present a variety of architectural solutions, although for the most part they use local materials as well as concrete. Walls are mostly made from clay brick (there a few built with stone) and for roofing the most common solution is a light wooden structure with clay tile.[3] The same design was used for several of the smallest settlements that included a T-shaped structure with two classrooms and a house for the teacher.[4] In larger settlements, the school stands out due to its scale and design, such as in Antúnez.

The program of the rural schools built by the Commission between 1947 and 1958 consisted of two classrooms (in some cases four), a small office, a storage room, a library and restrooms, and, as a separate structure the house for the teacher or teachers. At El Ceñidor the school included an outdoor theater and at Cenobio Moreno there were showers and changing rooms for use by local residents who did not have running water in their homes. Most schools also had a basketball court.

These schools share a series of characteristic related to the tropical climate. Most of them have shaded covered corridors on four sides of the building to protect the walls from the sun as well as a covered outdoor room between the school rooms and the bathroom which could be used as a theater or shaded play area. Often, these shaded areas were about half of the total surface of the school. The classrooms have high ceilings and high windows that helped with airflow to keep the classrooms cooler.

In keeping with Cardenas's interest in replacing the religion with education (and the church with a school), the school were meant to be visible symbols and places strategically within the settlements. The most notable example is the school at Llanos de Antúnez (a new settlement) which was placed in the center of a large roundabout (170 meters in diameter). The scale of the building in the rural context made it a point of reference for the community, located on the main boulevard. The school facades in the projects built by the commission articulated their importance and their relationship to the region with nods to local architecture. Even in the smallest communities, the entrance to the school was framed by brick columns that held a sign with the name of the school that set it apart from the low houses surrounding it.

4. CAPFCE AND THE RURAL SCHOOLHOUSE AFTER 1958

Between 1958 and 1964 with Pedro Ramírez Vázquez as general director, CAPFCE presented a standardized design for the construction of rural schools. Authorship of the design is attributed to Ramiro González del Sordo, Pedro Ramírez Vázquez and Jorge Campuzano Fernández in the pamphlet edited by CAPFCE.[5] Additionally, it is important to mention the participation

2. This continued into the 1960s as evidenced by documents signed (or finger-printed) by members of rural communities in which they commit to providing resources for their schools. Archivo Histórico de la Secretaría de Educación en el Estado-Michoacán, Serie: Escuelas Primarias. Sección: Dirección Federal de Educación. Subserie: Fundación y/o federalización de escuelas. Caja 107, expediente 1384.

3. In adjoining regions, a school was built of Wood. In Gámbara, in the municipality of Múgica the school was built with stone.

4. This model appears in: El Ceñidor (built with funds from the ejido), Pinzándaro, El Letrero, El Rosario, and Nueva Italia (with a slight variant that reduced the number of covered corridors).

5. Pedro Ramírez Vázquez, Aula Casa del Maestro. (Mexico City: SEP, 1959). Acervo de Arquitectura Mexicana.

of Manuel Teja and Juan Becerra who together with Ramírez established ECA, S.A. in 1959 who designed the structural prototypes for construction.[6]

The schoolhouse design used prefabricated elements that could be easily transported to rural areas and erected by the local community; CAPFCE presented with four options for construction using wood, brick, adobe or wooden slats (for tropical climates).[7]

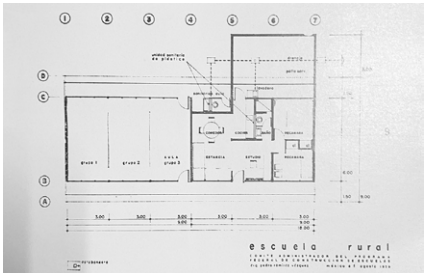
The design was a one-room school with the teacher's house under the same roof. With a surface of 108 square meters, it contained a classroom that measured 9 by 6 meters that could be divided into separate spaces for children at different levels in their education. The teacher's house of roughly the same area had a kitchen, living and dining space, a small study, two bedrooms and a bathroom and, to the back, a walled in patio. There were variants with two and four classrooms and the design became the basis for all school construction all over the country in the decades that followed.

The schoolhouse came in a package that included all the elements for the building. No element weighed over 50 kilograms, ensuring they could be lifted and put in place by the local community without the need for cranes. The entire package of structural elements and windows, and door frames weighed 4.3 tons. Instead of glass, windows were covered with translucid plastic that incorporated, maps and didactic images. Additionally, each school was provided with equipment (including a phonograph) and didactic materials.

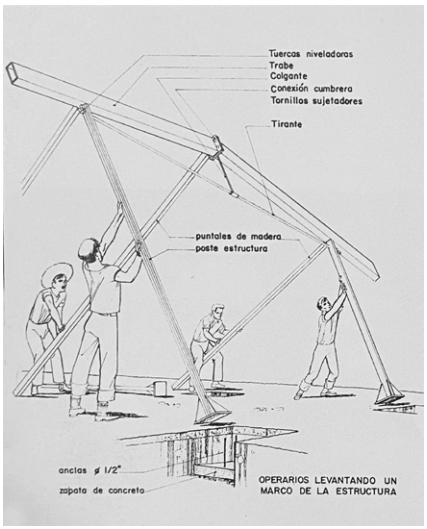
The design was implemented in 35,000 schools all over Mexico and emulated in other Latin American countries. In Mexico, the schoolhouse became ubiquitous and, with its low tile roof and small scale fit into the communities without standing out. Its placement in communities varied greatly, sometimes occupy lots on the outskirts of towns and in other central locations.

5. CONCLUDING REMARKS

The case of the schoolhouses built by the Tepalcatepec Commission in the hot lands of Mexico illustrates the struggle of local communities and their agency in getting financing and their participation in building and maintenance of their schools. Undoubtedly this generated a sense of belonging, even in the cases when the design was provided by the authorities. The prefabricated casa-aula gave continuity to the participation of local builders, even though the schools did not contain formal elements related to the local region. The use of local materials and the options given by CAPFCE did not make the schools "regional"; despite the stated proposal to wed local craft with national industry, the proposal was national in nature.[8] The design of furniture refers to crafts, but not specifically to the locales where the schools were built.



One of the most interesting differences that can easily be overlooked is the placement of schools. In the federal aula-rural program the schools were not usually centrally located, and their small scale made them fit into rural communities. This is in stark contrast to the program headed by Cárdenas in the Tepalcatepec where visibility was paramount. As part of a strategy to replace religion with education and the church with the school, the new schools –although not exactly monumental— became focal points for the



6. The recognition the project received in the Triennale in Milan in 1960 did not give credit to these participants. It is also important to mention the Silver Medal was given to Ernesto Gómez Gallardo for the design of furniture.

7. Ramírez Vázquez, Aula Casa del Maestro. It is important to mention the precedent of Rivadeneyra´s experimentation with prefabricated and standardized classrooms as head of CAPFCE from 1952 to 1958.

communities. There were given a hierarchical central place in the town layout and also included services that could be used by the communities: basketball courts, showers with dressing rooms for those who had no running water at home, theaters and even community kitchens in some cases. ■

Catherine Ettinger is an architect full-professor at the School of Architecture at the Universidad Michoacana de San Nicolás de Hidalgo where she has taught architectural theory, history and preservation since 1986. Her research interests lie in twentieth century Mexican architecture and the circulation of ideas in Latin America. She is active as a speaker in academic conferences and has published numerous books, book chapters and articles. (Facultad de Arquitectura, UNAM, 2023). She is an active member of DOCOMOMO México and currently secretary of the chapter. She is a level 3 researcher Sistema Nacional de Investigadores in Mexico and board member of the Society of Architectural Historians.

LEARNING THROUGH EXPERIENCE: JOHANN HEINRICH PESTALOZZI'S PEDAGOGY IN HANNES MEYER'S EDUCATIONAL BUILDINGS

RAQUEL FRANKLIN UNKIND
UNIVERSIDAD ANÁHUAC MÉXICO

ABSTRACT

Hannes Meyer first knew of Johann Heinrich Pestalozzi's pedagogical ideas while working on his Freidorf cooperative estate project. For Pestalozzi (1746-1827), education was vital to achieving humanity, the last phase of his conception of *Human Nature*. The social context was equally influential at that. The educator believed in a holistic approach where the Head, the intellectual, the Heart, the moral, and the Hand, the physical, must be stimulated.

His intuitive method privileged experience and perception through the senses. It benefited from close environmental contact and developed a healthy body. Moral values were expected to be instilled in the family circle, where the mother bore the primary responsibility of upbringing.

In 1926, Meyer and Wittwer stated their goals for the Petersschule: "No commanded study but rather experienced knowledge. No deformation of the spine but rather body care. No school cripples, but rather vital youth."[1] These were the architects' first references to Pestalozzi's agenda. To achieve that, well-lit classrooms, workshops, and bathrooms were included. A gym and two large, suspended terraces promoted physical activities in an avant-garde shape.

Pestalozzi's pedagogy was also implemented at the ADGB School. Conceived as a trade union training facility, it took those principles further. The connection with nature became stronger. Physical activity was central to well-being. Collective work was enhanced through brigades following the small circle theory, as reflected in the dorms.

Pestalozzi's ideas are notable in the children's home in Mümliswil. Through Pestalozzian methods, children were introduced to cooperatives, including a "Mother Gertrud" guiding the activities. Community participation was fostered mainly in the round room, where performances and discussions occurred. Thanks to the adequate installations in the building, hygiene was stimulated, and the natural environment of the Jura mountains was a central actor in learning by playing.

1. INTRODUCTION

Hannes Meyer first learned of the transformative ideas of the Swiss social thinker and educational reformer Johann Heinrich Pestalozzi (1746-1827) while designing Freidorf, the first cooperative estate in Switzerland. The community had envisioned establishing a Pestalozzi school[2] where children would learn in small circles, discovering through experience and developing physical strength as an essential condition for the healthy development of the mind. The ultimate goal was, however, to bring people to a moral state in which egotism would be superseded. In Freidorf, people would be reeducated as "new men" capable of coexisting in harmony with their neighbors.[3] Alfred Lei, one of the cooperative's founders, saw it that way: "When we move to Freidorf, we'll have to forget how we were raised until now and educate ourselves to become new people. It is pessimistic to think that people wouldn't get along in Freidorf."[4] The estate, they believed, "should be the beginning of a modern cooperative enterprise and serve as a role model and example of how our world should be built in small groups."[5] These learnings will eventually influence how Meyer conceived his role as an educator and designer. His work at the Bauhaus and his projects for education, the Petersschule, the ADGB School, and the Children's Home in Mümliswil will gradually incorporate principles that can be traced back to Pestalozzi.

2. JOHANN HEINRICH PESTALOZZI'S EDUCATIONAL APPROACH

Central to the vision of Freidorf was the education of individuals who could transcend their egotism and engage with the rules and benefits of the collective, much in the sense of Pestalozzi's philosophy. For him, education was the key to humanity, the way society shaped the person. Without it, people would get wild.[6] The "art of education," or "the art" as he called it,[7] was fundamental in raising individuals to the moral stage, the very last in his three-fold conception of *human nature* that could be reached "only after we have found and realized our life's task, which is beyond egoism, [and] lead a truly fulfilled life."[8]

Pestalozzi believed that ignoring social change was neither possible nor desirable.[9] Education should respond not only to man's natural physical and psychological faculties and needs but also to his social circumstances and himself.[10] It is in the inner circle of the house where these values should be instilled in the child in the first place. The school should advance those morals further through the example and love of the teacher to his pupils; it does not impose anything on the child but expands what is already in his nature.[11]

The Swiss educator conceived a pedagogical method that considered the child's cognitive psychology and social milieu.[12] The teacher's role is to foster those capabilities and to teach them the elementary knowledge to become "a fully developed intelligent moral person."[13]

He spoke in that sense of the head–heart–hand abilities to be cultivated. "Head," the cognitive, and "Hand," the physical strength and manual dexterity, supplemented that of the "Heart," meaning the "basic moral feelings of love, faith, trust, and gratitude, plus also the activity of our

10. José María Cabañas Quintana, "El Concepto de Naturaleza y de Estado de Naturaleza En Pestalozzi." *Revista Española de Pedagogía* 65, no. 236 (2007): 94. http://www.jstor.org/stable/23766004

conscience, our sense of beauty and goodness, [and] the ordering of our lives according to moral values."[14]

How to stimulate such abilities was the next step in the process. For that, Pestalozzi developed his method of *Anschauung*, or "method of intuition," i.e., the "direct knowledge of the object through the five senses; … the primacy of the direct experience of the individual"[15] instead of memorization.[16] Exercises in three main categories, number, form, and language, went from the concrete to the abstract; that was the Principle of Coherence,[17] where drawing played an essential role.[18]

Concepts of space and time were intrinsic to the child's mind in an underdeveloped way. It was the teacher's task to arouse intuitions of form so that, in the process, the child could recognize not only its outline but also its characteristics of color, texture, etc. At a later stage, he would also be able to inquire about its function, construction, history, etc., to interpret and consolidate knowledge.[19]

3. HANNES MEYER'S FIRST EXPERIENCES

In 1924, Hannes Meyer had the chance to experiment with such concepts when commissioned with the Swiss pavilion at the World's Cooperatives Exhibition in Ghent, Belgium. He explained his plan to the actor Jean Bard, hoping he would join him. He said: "Each country will expose its products. Personally, I have a more original idea. I would like to explain the cooperative principle to the public through a puppet theater of a particular conception. It would involve playing dolls on a human scale with real actors."[20]

Confronting the puppet with the human highlighted other oppositions, reminding us of some of Pestalozzi's terms: "social: Co-op versus anti-co-op, artistic: Naturalness versus truth. Here the natural movement of man, dictated by heart, brain, custom, affect, and intellect; there the emotion-free, shameless, and spiritlessly unrestrained, truthful attitude, and devotion of the puppet, absolute 'play.'"[21]

In 1926, Meyer published his text "The New World," reconsidering his position regarding architecture, history, and tradition, favoring universalism and functionality; he left Freidorf and partnered with Hans Wittwer. They participated in two architectural competitions that placed them among the avant-garde of the ABC group he had joined a couple of years before: the Petersschule and the Palace of the League of Nations.

4. THE PETERSSCHULE COMPETITION

K. Michael Hays recognizes the Pestalozzian basis for Meyer and Wittwer's entry into the Petersschule competition when he says: "The desired conditions are, first, Pestalozzian sociocorporeal ones: 'no commanded study but rather experienced knowledge. No deformation of the spine, but rather hygiene. No school cripples but rather vital youth!'"[22]

These were the aims of their project, but how exactly did they match Pestalozzi's theories? They responded to the Head-Heart-Hand trilogy. In Pestalozzi's method, learning through experience, especially observation,

was privileged over memorization or the traditional way of learning. The action of the hand was matched with the intellectual development of the head. The second deals with the physical response and instilling values in the pupil, such as orderliness, cleanliness, perseverance, etc.[23] Meyer takes it almost literally from Pestalozzi's writings:

> *The quiet I demanded when I was there and teaching was a great help towards my goal, as was the insistence on the physical posture in which they sit. …It is incredible how the insistence on such little details can give the teacher the basis for great ends. Unless they had seen it, no one would believe that a girl who has been allowed to run wild takes a first step on the road of moral development simply by becoming accustomed to holding her body and head straight for hours on end without letting her gaze wander.*"[24]

The third statement, "No school cripples but rather vital youth," probably goes in the sense of disqualification that both Pestalozzi and Meyer rejected. Everyone has a talent that should be fostered. Meyer would return to that idea during his Bauhaus period, saying, "Everyone has an aptitude for something. Life refuses no one. Hence, education for creative design engages the whole man, removes inhibitions, anxiety, and repression, and eliminates pretense, bias, and prejudice.[25]

How were they addressing such goals in the architecture of the Petersschule? First, a strong emphasis on physical development demanded ample spaces for exercise that, under the conditions established in the call, especially when selecting the site, could not be met. They believed the designated site was unfit for a modern school. The patio was too small, not even a square meter per pupil. Therefore, two suspended terraces would artificially expand the playground. The classrooms, playgrounds (covered and uncovered), and toilettes constituted a constructive unit (**Fig. 1**). The rest of the architectural program that got particular attention was composed of a teachers' room, a gym, a school pool, a kitchen, and an assembly hall. The optimal light for the classrooms had to come from a skylight; however, since there was no place for a single level, they had to reach a compromise, leaving only the drawing room on the upper level, with an eastern orientation for the rest of the classrooms. Spaces for body care, including the gym and pool, were located on the ground floor. There was also a room for manual work, and the collection was to be exhibited in vitrines on the first floor's hall. Finally, a modern constructive system of standardized concrete pieces and steel bridges for the terraces was to be supplemented with insulated lightweight walls, rubber flooring, etc.[26]

Meyer and Wittwer's project "Kompromiss" was disqualified in the first round;[27] nevertheless, it served, together with their project for the Palace of the League of Nations, as an example of Meyer's work that brought him to the Bauhaus.

Pestalozzi's learnings were also introduced in the school's curriculum once Meyer took over the Direction from Gropius. The workshops stood

at the core, while sports, the stage, and the band were incorporated as part of a holistic training of students. The vertical brigades, in which the more advanced students helped the younger ones, also derived from Pestalozzi's method of the small circle, which preferred to mix children of different ages and abilities in the same class to profit from comradeship.

5. THE ADGB SCHOOL

Those ideas were implemented in adult education at the Bauhaus and the ADGB School designed for the General German Trade Union Federation. After winning a competition, Meyer and Wittwer were commissioned with its construction in the forest of Bernau, near Berlin. Otto Hessler, the architect in charge of the program's development, established the expectations from the onset: "The building should be an example of modern building culture. It shouldn't be created as a school in the traditional sense, in an arbitrary form with the required number of classrooms, seminar rooms, living rooms, etc., but it should be exemplarily created in every sense."[28]

The training center was conceived as a place where workers could, for a short period of one to two months, learn not only about their trade or syndicalism but also socialize, improve their health through exercise, relaxation, and contact with nature, and, in Pestalozzi's sense, get over their egotism and engage in the community. Architecturally speaking, "in the organization of the school life, Meyer followed Pestalozzi's so-called 'Theory of the small circle,'"[29] alternating activities among the brigades to optimize the use of rooms, each with proper natural lighting. He included a gym, pool, and stadium for physical activities, a large aula, and a dining room with resting areas open to magnificent landscape views. The dormitories were distributed in four blocks of three floors, each for 30 brigade members and an extra one for communal activities (**Fig.2**). Five double rooms on each floor shared a bathroom at the end of the corridor. A color coding identified each building with a brigade, red, yellow, blue, and green, degrading the tonality in each floor to orient the users through the building or to indicate the hierarchy in the organization, thus enhancing the sensory perception of the participants. The blocks staggered according to the terrain's natural slope, and a glass corridor unified the complex, running from the dining room toward the classrooms and the gym. Four teachers' houses completed the design at the entrance. Bauhaus students participated in the construction and interior design, fostering the idea of learning through experience.

The building was inaugurated in 1930 and functioned as planned for only three years before falling under Nazi rule and, later, under the GDR, fell into decay. The restoration works ended in 2007, and it was inscribed in the UNESCO World Heritage list in 2012.

6. THE CHILDREN'S HOME IN MÜMLISWIL

Upon returning to the homeland in 1936 from the Soviet Union, Meyer was again commissioned with a project for the Swiss Cooperative Union. Bernhard Jäggi, the cooperative's president, donated the building for a children's home

in his hometown, Mümliswil, to introduce kids from all social strata to cooperative life and principles through Pestalozzian methods. For the first time, Meyer acknowledged a direct response to the educator in his design:

> *In the social sense, implanting fundamental cooperative ideas in the children through new means guided the donors. The home can host between 24 and 30 kids, making up the 'family cooperative circle.' in Pestalozzi's sense, having at the center a 'Mother Gertrud' as a director who, together with a teacher knowledgeable in sports, leads the educational work.*[30]

The children were to stay between two and three months, with a preference for those with weak constitutions who would benefit most from nutritious

food, hygiene, culture, and sport.[31] The building was designed accordingly. The rounded room that articulates the two aisles was the meeting room where children performed theater pieces or conducted their assemblies **(Fig. 3)**. Simultaneously, the terrace on top of it, with extraordinary views of the village underneath, was used for the morning exercises. There were double rooms for the children in one of the aisles, while adults occupied the perpendicular one. Well-equipped bathrooms enhanced hygiene, which was promoted as part of their educational process. Following Pestalozzi again, Meyer explained that "in its psychological functional scheme, an effort in compensating the collective demands with the individual needs has been made. Since any social link is endangered when the individual's life is disdained."[32]

The building, made out of local materials with local handwork, provided the children with spaces for manual activities, recreation, body care, double bedrooms on the children's aisle, and an aisle for adults' facilities. Pestalozzi's spirit was present during each activity. The building suffered some alterations throughout the years, most significantly adding a room on the rounded terrace (**Fig.3**). It served several functions throughout its history, including an orphanage and a women's club. Today, it is part of the Fluri Foundation and is a museum documenting the history of the Swiss orphanage system.

7. CONCLUSIONS

Meyer inherited many of Pestalozzi's ideas regarding education and society. The intuitive method, the small circle, and the attention to the Head-Heart-Hand were but a few. He had the opportunity to respond with architectural means to the demands of a reformed education system that privileged experience over memorization and fostered physical, intellectual, and moral strength with different emphasis in each project: body strength and experience learning in the Petersschule, the small circle in the ADGB School and the "Mother Gertrud" in the Children's Home. ■

INFRASTRUCTURES OF CHILD-CARE: ESTABLISHING THE MODERN LANGUAGE OF ZAGREB'S SCHOOLS IN THE AGENCY OF IVAN ZEMLJAK

MIA ROTH-ČERINA
FACULTY OF ARCHITECTURE, UNIVERSITY OF ZAGREB

ABSTRACT

The evolution of the urban landscape in the modern era, particularly regarding the role of buildings framing social infrastructure, embodies a deeper societal transformation in the conception of education that took a most significant shift during the first half of the twentieth century. This transition is underscored by a parallel advancement in pedagogical paradigms and architectural design, where progressive educational models find resonance in the spatial configurations characterised by openness, transparency, health and humanism. In the Croatian context, the interwar period witnessed a novel architectural language with a social ambition, particularly manifested in elementary and preschool educational settings.

While several renowned architects contributed with noted examples, the spatial articulation of education in Zagreb will be significantly inaugurated through the work of Ivan Zemljak. His engagement with international architectural tendencies, coupled with his keen interest in public health concerns, facilitated the convergence of diverse demands inherent in the design of modern educational spaces. His tenure as the head of the City Building Department afforded him the opportunity to apply and refine his expertise, resulting in the construction of numerous elementary schools and associated child care facilities across Zagreb.

The architectural legacy of Zemljak, exemplified by his adept fusion of modernist principles with vernacular sensibilities, underscores a dynamic evolution in architectural expression within the Croatian context. Over a span of a decade, his designs transitioned from cubist austerity to an embrace of local architectural idioms, articulating a unique amalgamation of the open-air education movement's pavilions and regionalism.

The symbiotic relationship between pedagogy and architecture, as exemplified by the work of figures like Zemljak, elucidates a broader narrative of societal evolution wherein educational environments reflect shifting cultural, pedagogical, and architectural paradigms.

1. INTRODUCTION

The transformation of the urban environment in the first half of the 20th century, particularly concerning buildings of social and educational infrastructures, went beyond embracing modern principles. A profound change in how the child was viewed within the modern city, following a simultaneous progress in pedagogy and developmental psychology, aligned with a new spatial language prompted by needs for exposure to air and light particularly evident in the open-air movement. An educational space catering to freedom of movement and a flexible curricular schedule found its answer in an overarching hygienisation of the built environment.[1] New forms of teaching, enabling active child participation and direct contact with nature, indirectly introduce a range of spatial consequences, which alter the school space in various pedagogical models through different ways. Recognizing the child's individual abilities and their natural need for work and activity was the common denominator of reform pedagogy movements emerging at the end of the 19th and beginning of the 20th century. Providing an alternative to traditional schooling were various pedagogical approaches promoting artistic education, manual work, education in and by nature, articulated in an array of models and methods. Some had a profound influence on the inner formulation of educational space. However, the one with the furthest reach in terms of reframing the space of the school became the one whose pedagogical and philosophical origin was surpassed by the alarming state of health in urban children – the open-air education movement. The school building, until the beginning of the 20th century, was a formative element of urban identity, defining its dominant role in outward spatial articulation and confirming social hierarchies in its interior, with high window-sills and fixed row-seating. The pavilion school catering to the fundamental reform of curricula[2] enabling an intense communication with the outdoors prompted a substantial reform in the role of the school-building in an urban environment, only to be affirmed by the simultaneous development of modernism's postulates.

2. A MUTUAL DEVELOPMENT: ARTICULATING GOALS OF MODERN EDUCATION AND THE LANGUAGE OF MODERN ARCHITECTURE

The shift in education's spatial expression is marked by a concurrent progress in pedagogical approaches and architectural design, where innovative educational models resonate in spaces characterised by openness, transparency, health, and human-centred principles. This can be observed in the alignment of parallel congress series defining the principles of modern architecture and healthy, child-oriented education. Postulates of both CIAM and the Congresses on open-air schools converge by the end of the 1930s. The Third CIAM Congress was held in Brussels in November 1930, and the Second International Congress on Open-Air Schools happened there in 1931.[3] The goals of achieving educational spaces featuring ample light, fresh air, providing freedom of movement were expressed in both.

The application of the conclusions of the Fourth CIAM Congress, held in 1933, implicitly fulfils the requirements of the open-air education movement.

3. Châtelet, "Le mouvement international des écoles de plein air", in *L'école de plein air - Une expérience pédagogique et architecturale dans l'Europe du XXe siècle"* 21-38

The Third Congress on Open-Air Schools formulated concrete requirements to the location and design of open-air schools, many of which were already present and extensively affirmed in examples of open-air schools built by that time. These two conferences held before WWII mark the conclusion of a long and fruitful experimental period in education and architecture intended for it – at the dawn of WWII, initiatives for the establishment of open-air schools in Europe diminish, as its postulates became absorbed into the ubiquitous demands for the modern post-war school.

3. RECEPTION OF REFORM PEDAGOGY AND ESTABLISHMENT OF ORGANISED CHILD-CARE IN THE CROATIAN INTERWAR CONTEXT

The influences of progressive education in Croatia were present but introduced at various places in pre-school institutions and schools. The implementation of new educational practices faced challenges, especially in traditional schooling, while pre-school institutions proved more agile. Experimental schools, established from the mid-30's onward, served as laboratories for implementing new pedagogical methods.[4]

The most widespread type of institutions catering to children outside of obligatory education in Croatia before WWII were children's shelters, intended for proletariat's children aged three to twelve, which had nowhere to go while both parents were working, both pre-schoolers or young schoolchildren. In Zagreb, after World War I, the number of children unattended during the day increased rapidly. Shelters were primarily caritative, founded next to schools. Their architecture regularly showcased principles of modern educational goals expressed in spatial configurations, particularly the influence of the open-air movement, aligning with their caritative and health-oriented function. In terms of built infrastructure, they are the originators of a newly constructed network of child-care facilities, many maintaining their role of kindergarten to this day.

4. THE ENGAGED ARCHITECT: SCHOOLS AND SHELTERS OF IVAN ZEMLJAK

The neo-classicist school-building was foundational in the identity of many Croatian towns and cities built during the Austro-Hungarian empire. The period between two wars witnessed a new kingdom, a rapid rise in urban populations caused by worker influx, and a modern articulation of new neighbourhoods. Zagreb was experiencing growth and social infrastructure became the focal point of interest in both its municipal infrastructure as in its progressive architectural scene. The reconsideration of spatial frameworks that would meet the pedagogical demands found in modern schools and children's shelters coincides with the involvement of Croatian architects in CIAM and the acceptance of "modern architecture as a means of fighting for new social and economic relations."[5]

Zagreb witnessed intense development between 1918 to 1941, amid significant social segregation and housing quality decline. Confronted with unprecedented challenges like overpopulation and disease, city authorities worked to alleviate hardships during economic crises. In line with policies

5. Premerl, "CIAM i naša međuratna arhitektura", 50-52

promoting preventive medicine and public education, the state regulated the construction of buildings for social standards through laws and guidelines. According to the Pupil Health Protection Law of 1930, schools were obliged to ensure hygiene for pupils and provide conditions for the physical development of healthy, as well as weak and sick children.[6] Similar requirements were outlined in the National School Law of 1929, which mandated that schools must have "classrooms and workshops according to hygienic and pedagogical rules" and that "the buildings of public schools must be in healthy locations; dry and bright (...)."[7] Both laws imply green areas, playgrounds, gymnasiums with changing rooms and showers, as well as southern or eastern orientation and cross-ventilation of classrooms.

The year 1930 thus represented a significant turning point for the inauguration of the modern language of architecture in realising the goals of contemporary education, and the conveyor of this shift was the architect Ivan Zemljak. His position as head of the city's Building Department in the Zagreb City Council allowed him to validate the possibilities of spatializing modern educational plans and programmes[8] to be "a mirror of the pedagogical approach to the child."[9] The municipal Building Department controlled and shaped the role of schools in burgeoning new parts of Zagreb. The city's construction policy prioritised educational institutions in new neighbourhoods, and in the work of Ivan Zemljak, they take on a didactic role both within their function and in relation to the neighbourhoods where they emerge as modern, enlightening focal points.

The schools and shelters Zemljak built within a decade – 1930-1940 – defined a rapidly growing Zagreb's periphery, soon absorbed into the city. His work bridged the defining quality of educational buildings at the turn of the century in terms of identity establishment, but more importantly, showcased the fundamental principles of the modern school – ample light, open spaces, movable furniture, and polyvalent communal spaces.

The shelter Zemljak designed in the worker's suburb of Trešnjevka was the first modern children's shelter, built next to a school[10] in 1930. The shelter was the first testament of his influence by neoplasticism, also reflected in the project of the school in Jordanovac, which Zemljak was simultaneously designing.

The school on Selska road is one of the landmarks of Croatian modern architecture. A complex of three volumes enclosed a large green space with a swimming pool used by suburban children outside of school weeks. A municipal shelter for children within the Selska school was opened in 1931. The composition of three interconnected volumes dominated the working-class landscape; two tall wings with a central volume of the hall and shelter, connected by an open portico. The shelter was intended for preschool and elementary school children aged 3 to 12, and during school holidays "for the accommodation of holiday camps." The open space and the hall were designed for the community and intensive use during holidays and weekends: an open-air pool, a football field, porticoes; the hall was equipped with a cinema projector, radio, and stage.

9. Maroević, "Arhitektura Ive Zemljaka", 72-80

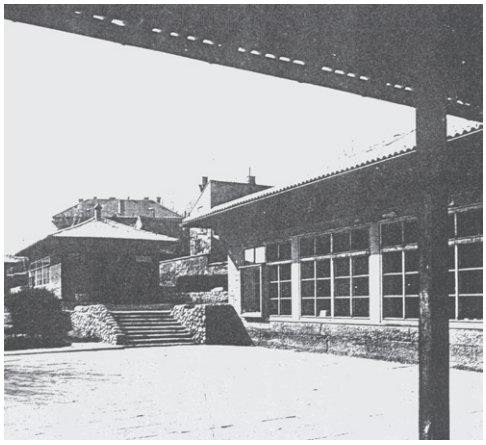
10. Also designed by Zemljak, however, a couple of years earlier, still bearing a neoclassicist idiom.

The same year, Zemljak completed an elementary school in the hilly eastern rural part of Zagreb's periphery. His shelter next to this school, built a few years later, responded to the current pedagogical and hygienic requirements regarding children's and outdoor spaces, with a scheme he will vary in several later projects: a longitudinal comb-like layout in which classrooms with three facades and corresponding terraces alternate in a regular rhythm. The design of the areas around the school, with playgrounds, meadows and orchards, were adapted to all-day stay encouraging work and play outdoors.

The shelter next to the neo-classicist school in Lašćina, completed in 1938, was the most radical application of the pavilion type in Zagreb's educational architecture, evoking the roots of the open-air movement. Zemljak was tasked with building three units for 40 children each, a dining room, and the janitor's apartment. He freely arranged a complex of four freestanding pavilions – three classrooms and a dining room – following the sloped terrain and connecting them with a covered walkway. His aimed for autonomy of each group containing all functional elements: entrance, cloakroom, toilets, showers, and a 70 m^2 classroom space.[11] In the Lašćina shelter, Zemljak interpreted the modern theme of the classroom pavilion through an idiom of local traditional architecture, making it a "turning point in the development of Zemljak's design expression: a gradual departure from the strict language of the international style and a shift towards organic architecture with the use of traditional and vernacular elements."[12] The pavilions' roofs are sloped, with eaves and wooden beams, and facades, covered in brickwork coated with a thin layer of plaster. The spaces between the pavilions and open terraces organically blend with the terrain. Height differences are addressed with dry stone walls, and the articulated garden is further animated with bird feeders, beehives, benches, wells, and play equipment.

At the same time, Zemljak had completed a school with an integrated shelter in Rapska Street. An original concave south-facing wing, aimed to create a sense of community through a geometrical gesture. Several other schools, without integrated shelters, were built by Zemljak during the 1930's, all applying the principles of open, light, hygienically and technically sound edifices. One of them – the school in Koturaška – was selected in 1936 as an experimental school for curricular development and teaching of new pedagogical principles.

Finally, Zemljak's school with a shelter in Knežija from 1940 combines an elementary school with a comb-like pavilion-shelter. Here, he combines the expression of Lašćina with the spatial scheme of Jordanovac – although the school is two-story, and the shelter pavilions are on the ground floor, arranged in syncopation with terraces, the roofs are pitched, and the eaves are pronounced. Like all previous examples, the shelter in Knežija is still used as a space for preschool children's activities.



5. CONCLUDING REMARKS

Educational buildings were the laboratory of a new approach to the built environment as much as the spatial expression of a new humanism directed

11. Zemljak, "Nova dječja skloništa u Zagrebu", 59-65

towards its youngest. The development of educational institutions in Croatia before WWII reflects this dynamic interplay between pedagogical theories, architectural innovations, and societal needs. Reform pedagogy influenced the evolution of both pre-school institutions and traditional schools, albeit at different paces and for different reasons. The swifter shift in pedagogical and spatial investigation was introduced in the network of facilities catering to younger children outside of obligatory education: shelters as precursors of the built infrastructure of child-care.

The implicit social, emotional, pedagogic and hygienic needs of Zagreb's growing worker neighbourhoods found their matching architectural response in a decade of realisations by Ivan Zemljak. They reflect the influences of current movements in pedagogy and modern architecture, coinciding with them and gradually adopting a local idiom over time in his interpretation. In an original authorial language, the newly built infrastructure of education in Zagreb embodied all modern requirements aimed at the well-being of children in cities – fresh air, sun, hygiene – as well as pedagogical requirements. His personal interest in issues of pedagogy and public health accompanied a clear architectural expression which, in less than ten years, evolved from

a cubist austerity towards modernist regionalism, employing vernacular idioms and materials in an educational environment rich with tactile spatial experiences. The empathic approach, creating numerous opportunities for spontaneous appropriation by generations of schoolchildren, has survived as a contemporary example of educational space used in the same way as intended, almost a century later. It is worth mentioning that all of Zemljak's spaces from that period are in the same function for which they were designed, and are still highly rated by users in terms of suitability for the content they house. Many of Zemljak's schools and shelters from the 1930s – all exceptional achievements in educational architecture – are all listed in the Register of Cultural Heritage of the Republic of Croatia. ■

BIOGRAPHY

Mia Roth-Čerina, PhD, is a Croatian architect and professor at the Faculty of Architecture, University of Zagreb. Her practice is led in partnership with Tonči Čerina, with whom she has received numerous national and international awards. In 2023 they curated the Croatian pavilion at the 18th Venice Architecture Biennale. As an author and co-author, she publishes articles, studies, textbooks and books. From 2010 to 2017, she was the Croatian delegate of the international work program Architecture & Children at the UIA (International Association of Architects). In 2018, and again in 2022, she was elected to the council of the European Association for Architectural Education.

CHESTE WORKER UNIVERSITY: DESIGNING A MODERN EDUCATIONAL CENTRE TAILORED FOR CHILDREN

FERNANDO USÓ MARTÍN
UNIVERSITAT POLITÈCNICA DE VALÈNCIA

MAITE PALOMARES FIGUERES
UNIVERSITAT POLITÈCNICA DE VALÈNCIA

ABSTRACT

This paper examines the intersection of architecture, pedagogy, and social and political context in shaping Modern Movement educational environments, through a case study of the Cheste Worker University in Spain, designed in 1967 by architect Fernando Moreno Barberá.

Under the premise of transforming society through educational policy, the Franco regime implemented a socio-educational programme for working-class youth starting in 1955, aiming to boost the national economy by enhancing the qualifications of the workforce. The implementation of this training programme led to the construction of twenty-one Worker Universities with Cheste planned as the largest one: a reference Guidance Centre for all the country catering to over 5,000 inhabitants aged between 11 and 14. Residence in the huge educational complex was on a boarding basis, forcing simultaneous and synchronised daily activities.

The result is a large-scale project that unfolds a personal interpretation of the compositional principles of the modern movement, with a predominance of the aesthetic possibilities of reinforced concrete structures. Moreno Barberá approached its design based on sociological studies and under the premise of "demassification", aiming to foster empathy with students to ensure their well-being and the smooth operation of the centre. This special sensitivity is perceptible across all its scales, encompassing site layout and landscape, architecture or interior, furniture and graphic design, with a focus on placing the young student at the forefront of design considerations and the integration of innovative pedagogical approaches.

Using archival research and architectural analysis, this paper reconstructs the design process and intentions behind the different buildings, common spaces and landscaping.

The findings highlight the importance of considering user experience and pedagogical innovation in the design of educational environments, revealing how architecture can facilitate effective learning environments and support the holistic development of students, offering insights that resonate with contemporary discussions on school design and educational practices.

1. THE SOCIO-POLITICAL CONTEXT: THE FALANGIST SOCIO-EDUCATIONAL PROJECT

In the final years of the Spanish autarchic period, when the interventionist economic policy and international isolation were pushing the Francoist regime into a critical situation, the national syndicalist-Catholic movement decided to promote the construction of a series of worker training centres for the industry, aimed at boosting the weak Spanish economy. Training professionals in various branches of industry also aimed to placate a growing social discontent – as a concession to the working class – and to project a certain aura of modernity onto the anachronistic and underdeveloped dictatorship.

Pressed by the need for qualified labour for new, more specialised jobs in an industrial fabric in activation, these new educational institutions sought to reverse a trend that showed data of a very high dropout rate after elementary education. Consequently, one of the main objectives of the Falangist educational policy was the training of the working class, while ensuring tight control of society through the ideological indoctrination of the child population, silencing any potential political or social demands.

The creation of the Spanish Worker Universities was first mentioned in a speech by José Antonio Girón de Velasco - Minister of Labour between 1941 and 1957 - where these centres were described as an ambitious project aimed at the professional, technical, and human training of workers and their children, although the project of new macro-institutions was consolidated and institutionalised alongside the Economic Stabilization Plan of 1959.

2. PEDAGOGY: THE SINGULARITY OF WORKER UNIVERSITIES

From the 1950s onwards, a process of greater flexibility and pedagogical modernisation began in Spain, albeit always under the same initial ideological principles. The main innovation of the Worker University project was the incorporation, within the new teaching programme, of a cultural and humanistic component that the existing centres dedicated to vocational training did not offer. Their designation as "universities" – not without controversy – reflected the humanistic and globalising nature of the new professional education, being outlined as superior institutions.

For the Francoist regime, vocational training, therefore, became the means to offer the greatest prospects for the working-class improvement and social progress, dignifying the labour condition and allowing workers to access professional positions. Education at the Worker Universities was completely free. The Mutualities covered the cost of student scholarships including their corresponding maintenance or accommodation in case they were boarders: food, clothing, travel from the family residence to the Worker University and vice versa, school supplies, enrollment fees, toiletries, textbooks, heating and lighting, use of laboratories and workshops, practice materials, sports facilities and equipment, laundry and clothing maintenance, correspondence of students with their families, medical and pharmaceutical services, certifications, and academic degrees.

In short, the student's family was relieved of any direct or indirect burden that could arise from their schooling.

3. WORKER UNIVERSITIES EXPANSION

A total of twenty-one Worker Universities were constructed across the nation, and were distinguished during their operational years due to their undeniable social and economic role.

The first Worker University to become operational was the one in Gijón (1946-1957), intended for the training of about a thousand students. The architect, Luis Moya, was commissioned to create a "monument to labour" and embraced monumental and classical architecture as the only dignified style capable of expressing the "new order." However, by 1955, Moya's solitude in these approaches became apparent, consolidating the shift towards a more architecturally rationalist language. The changes made to this initial experience will impact the relationship of future centres with the environment, adopting much more permeable dispositions with the natural surroundings. It is interesting to compare the architecture from the Universidad Laboral de Gijón (or Worker University of Gijón, as it would be known in English) with the projects that were undertaken immediately afterward, such as those in Seville (OTAISA, 1949-1954), Córdoba (Miguel de los Santos, Francisco Robles, Daniel Sánchez Puch, and Fernando Cavestany, 1952-1956), and Tarragona (Luis Pera Buesa and Manuel Sierra Nava, 1953-1956). These projects use references, materials, and compositions closer to modern architecture than to the official models of Francoism, and they inspired architecture that was built following international trends. Thus, educational architecture aroused enormous interest among Spanish architects, making it a field of architectural inquiry.

4. CHESTE WORKER UNIVERSITY ARCHITECTURE

The Cheste Worker University, designed by Moreno Barberá in 1967, was the first institution in Spain for the training and guidance of students funded by Labour Mutualism, representing a significant difference compared to the centres founded up to that point. What was originally conceived as a Worker University for the vocational training of young people in the region would become a "Centre for Guidance of Worker Universities," constituting a genuine student city with a capacity for 4,800 students, more than double that of larger centres like Seville or Gijón.

Following a boarding school regime, these children between the ages of eleven and fourteen were to complete the first two courses of the training plan at the Orientation Centre. Based on the aptitudes they demonstrated, they would then be directed to the various disciplines taught at different Worker Universities. This extensive educational complex served as the mandatory gateway to the educational system of the Worker Universities. It directed all newly enrolled students to transition to one of the other centres after levelling up in terms of knowledge and providing personal, academic, or professional guidance to ensure their success in the scholarship system.

This system aimed to mitigate the significant differences in educational levels among students, a task entrusted to Cheste for standardisation.

According to Luis Illueca Valero, the first Rector-Administrator of the Centre for Guidance of Worker Universities in Cheste, the institution's objective was "to be a community, but an educational community: not a military camp, not even a boarding school, nor a replacement for the family. It is an attempt to create a new society through personal achievements in coexistence, through the experience of decision-making, and by creating a youthful way of dealing with each individual's personal problems. [...] It is a way of trying to empower the individual by exposing them to an enrichment of material means and above all, communal experiences."[1]

In the project report, Moreno Barberá provided a scale for the programme by comparing it with demographic data from 1967. He stated, "Of the 9,202 municipalities in Spain, 88.6% have fewer inhabitants than the projected University." Consequently, the project was conceived on an urban scale, addressing all the needs of a population of this size with the particularity that "all inhabitants did the same thing at the same time and together."[2] The institution stressed the importance of "de-massification," meaning that students should not feel like they belong to a mass of 5,000 people all doing the same thing. Instead, they should live in autonomous groups, each with their own activity independent of the others, for which the activities that all students must participate in simultaneously were carefully studied.

In May 1967, a group of teachers and psychologists developed a preliminary needs assessment regarding facilities, dependencies, and services required for a centre of this type. Such an assessment served as the basis for the architectural draft, which was already entrusted to Fernando Moreno Barberá. Experts from the Worker Universities in operation at that time participated in the group. The ambitious initial programme, with successive modifications and observations made to the preliminary project, included extensive provisions that Moreno Barberá eventually grouped following a strictly functionalist scheme: Public Area, Teaching Area, Dining and Services Area, Residential and Expansion Area.

Additionally, all these different uses had to be structured in a way that established ideal functional relationships between the buildings: "Efforts should be made to minimise the distances travelled by teachers and students. Avoid mixing visitors with students. Group buildings in such a way that the teaching function does not interfere with the students' lives, so that they can forget about the existence of classes when they finish class hours and live peacefully in their residential areas."

Moreno Barberá insisted on the necessity to find a suitable location to accommodate such an extensive child population, and engaged in the search for the final spacious plot of land on Alto de la Loma in Cheste. To ensure construction efficiency, both in terms of material economy and time, the project was governed by a module of 1.60 metres, derived from the reference unit of the student's desk, measuring 0.80 metres. Therefore, the adaptation of architecture to the scale of children was the fundamental basis for the project.

1. Transcription of the documentary "La Universidad Laboral de Cheste" (RTVE, 1972). Doctor in Pedagogy, this Valencian carried out a divulgative work around his pedagogical approach through several publications such as "Padres e Hijos" (Aula, 1967), "Cómo enseñar a nuestros hijos" (Banco de Vizcaya, 1967) or "Una experiencia de organización educativa" ("Notas y Documentos" Collection, Dirección General de Enseñanza Primaria, 1970).

2. The following quotations that appear in the text are the direct testimony of Fernando Moreno Barberá, either extracted from the original project documents (1967-70) or as transcriptions of the lecture given at the ETSA-UPV in 1991.

4. 1. A MECHANISM FOR AN EXTENSIVE PREADOLESCENT POPULATION

Moreno Barberá's project incorporates psychological strategies to address the well-being of the unique resident population. In a brief text, Moreno Barberá outlined the main ideas underlying the proposal presented: "Architecture must adapt to man, in our case to the young person. Buildings are for people, to be used and inhabited by people. It is necessary to think of them when designing, to feel as one would feel when walking through them, when living in them. Anticipate and even provoke the reactions that, according to their psychology, the inhabitants of each building or complex will have when approaching it or moving within it. Many times, as in the present case, human beings are grouped into higher-order social units, to which all their activities must be organised: [...] A disciplined life, on one hand, such as that of education. Another ordered by the needs of the community, such as meal and sleep times."

The educational institution was designed to function as a large social machine in which each architectural piece was arranged as efficiently as possible from a distributive standpoint, guiding the constant movement of users between different functions. The goal was to create a large-scale urban mechanism to organise the lives of this high number of people while including de-massification mechanisms. During their activities, the large human group had to be divided into units of a maximum size of 200 people, which would make it more easily manageable and recognisable: the College. The sense of belonging to a group becomes a driving force in architectural design, both for its functional and emotional implications. Thus, the 4,800 students were distributed among 24 Colleges, each assigned their own independent spaces in residences, classrooms, workshops, and dining areas.

By way of its dynamic organisation, the ensemble made up of the four dining halls and the services building stands out as the most significant example of the de-massification attempt that pervades the entire project. In this case, it was the only area where approximately 5,000 people had to coincide at the same time three times a day, as the establishment of meal shifts had been dismissed due to numerous inconveniences. The architect decided to move away from the model of large communal dining halls "due to their depressing aspect" and, consequently, chose to divide the programme into four independent dining halls, each with 1,200 seats. Furthermore, each of them would be built in a circular shape encompassing garden courtyards – two of which were circular and two quadrangular – so that diners would never see everyone at once. Additionally, each college – a group of 200 students – would be separated by partitions. In these layouts, the design of furniture played a prominent role in aiming to influence the creation of closer human relationships. This also extends beyond the strictly architectural realm to permeate all scales of design, including even signage. In fact, the artist J.M. Cruz Novillo designed the emblems of the 24 colleges identifying each one with a colour and element from the natural world. Moreno Barberá's interest in bringing architecture together with art is noteworthy, with collaborations from visual artists such as Javier Clavo

being commonplace—a recurring theme in modernity since the avant-garde movements established strong interdisciplinary connections.

4.2. FREE INDIVIDUAL LIFE

At the same time, the architect considers it essential to have "expansion" spaces for leisure time, where boarding students can have an environment conducive to individualism: "Life during free or leisure time must unfold in spacious, informal spaces, where one can lose oneself, have freedom of movement and initiative, where one can find small adventures, spaces that are part of the landscape."

The explicit mention of the landscape scale is by no means accidental. In fact, it was precisely the need for open spaces –beyond the minimum requirements demanded by educational regulations for playground space– that was the most cited argument by the architect in the search for the project location. The architect's personal commitment to obtaining an optimal location with favourable conditions, surrounded by extensive wooded areas, is very

significant. This would enable students to "lead their own lives independently of others, even to isolate themselves without encountering the rest."

Seen through the lens of a sensitive approach to subjective experience, the manipulation of the rugged profile of the natural topography takes on new meaning, utilised to conveniently position the different pieces of the complex on the natural promontories, staggered and grouped by function. The architectural forms, appearing as three-dimensional voids, are scattered among the vegetation, adapting to the contour lines, and conveying a sense of flexible order. In this way, an environment is created to allow the student's personality to develop. A defined but seemingly free natural space, anchored to the random rules of nature, can positively influence students transitioning from childhood to adulthood. And within this vast open natural space, the buildings, with small, enclosed environments, seek to provide places conducive to introversion "to listen to music in small groups, to meet with friends, to plan outings or sports, or to come up with ideas like releasing a mouse in the next class. [...] The aim is for students to be able to forget all their teaching problems outside of class hours."

Moreno Barberá paid special attention to pedestrian circulation, which became a prominent architectural element: "One of the established problems was the need to decongest, as the 5,000 guys came down [at once] from the residential area through large, covered walkways so they wouldn't get wet when it rained." Adapting to weather conditions materialised in the form of reinforced concrete roofs that, like ribbons at just the right height and of a generous size, which colonised the territory to create spaces for socialising and coexistence. It brings to mind Latin American experiences such as Oscar Niemeyer's long and undulating canopy at the Ibirapuera Complex (1951) in São Paulo, or even his earlier canopy at the Pampulha Casino (1942), and above all, the sculptural covered walkways (1952-1953) by Villanueva at the Ciudad Universitaria de Caracas (or University City of Caracas, as it is known in English). But Moreno Barberá, more a builder than an artist, felt comfortable working with simple straight lines in a solution akin to the covered walkways by Mario Pani and Enrique del Moral for the Ciudad Universitaria (or University City, as it is known in English) of Mexico City (1948-1953). ■

PEDAGOGICAL EXPERIMENTATION AND MODERN ARCHITECTURE: EXPERIMENTAL HIGH SCHOOLS IN SANTIAGO, CHILE[1]

URSULA EXSS
PONTIFICIA UNIVERSIDAD CATÓLICA DE VALPARAÍSO

ABSTRACT

This research identifies architectural innovations from a selection of experimental educational establishments in Chile, with school buildings designed between 1950 and 1962. The article analyses the architectural value of these works in relation to the challenges faced by school architecture in the 20th century.

Experimental high schools have been vastly documented as valuable examples of educational experimentation that followed reforms from the 1920s and 1930s in Chile. Nevertheless, the relationship between pedagogical aspects and architectural space has received little attention. This paper analyses the experimental educational programme through its architectural projects: Manuel de Salas High School (1950), Darío Salas High School (1950), and Gabriela Mistral High School (1946). It utilises analytical drawings and dense descriptions of unpublished archival sources (architectural plans, photographs), as well as direct observation *in situ* of school facilities at the present time.

The results demonstrate that the architecture of Chilean experimental high schools gradually progressed towards a formal differentiation of their buildings in response to the increasing complexity of the school programme, which sought to be expressed in a visibly modern architectural form, and move beyond strictly functional requirements.

1. INTRODUCTION

The history of modern school architecture in Chile has focused on public buildings with significant urban presence, as well as on private educational establishments that introduced modern architectural principles. Among Chilean public architecture, notable works include those centred on the projects of the Ministry of Public Works, with remarkable school palaces from the early 20th century, and more abundantly, the works of the Educational Establishments Construction Society (*Sociedad Constructora de Establecimientos Educacionales*) from the late 1930s onwards[2].

The cases analysed were exceptional public establishments, as they responded to an experimental pedagogical guideline.

A lengthy debate on an educational reform initiated in 1928, followed by a counter-reform in 1932, resulted in the separation between regular establishments and others that would be expressly created as experimental.[3] The latter would be responsible for testing various innovative pedagogical practices of their time.[4] Once these practices were supported by scientific evidence, they could be applied to other common establishments.

The experiments conducted at primary education level have provided interesting insights into the learning methods tested at that time, and the resulting changes in spatial dynamics, both inside and outside the classroom. These methods were implemented in pre-existing buildings, conceived under the conventional teaching model – spatially non-experimental.[5]

The experimental pedagogical discussion at secondary level, on the other hand, combined the renovation of existing establishments with the creation of new ones explicitly designed to accomplish the experimental mission. New buildings would be aligned with the requirements of the experimental educational programme. This research investigates the relationship between experimental pedagogy and architectural features, aiming to understand the interaction between their modern conceptions. The hypothesis guiding this research is that educational experimentation gave way to a field of architectural exploration related to pedagogical aspects.

The methodology consisted of a documentary review of the main pedagogical guidelines of the selected establishments, primarily based on secondary sources, and a dense description of the architecture and analytical drawing, considering the architectural programme and the formal features of the school complex, as well as a selection of specific facilities.[6] This was based on primary documentary sources: blueprints, project reports, periodical publications, and historical photographs.

The following results are presented, focusing on the analysis of three cases:

- Manuel de Salas Experimental High School (1950)
- Darío Salas Experimental High School (1949)
- Gabriela Mistral Experimental High School (1946).

2. THREE ARCHITECTURAL PROJECTS FOR EXPERIMENTAL HIGH SCHOOLS

2.1. MANUEL DE SALAS EXPERIMENTAL HIGH SCHOOL

The Manuel de Salas Experimental High School was established in 1932 by Amanda Labarca, who was the General Director of Education at the time. It introduced pedagogical experimentation to the secondary level after four years of experience with the primary education cycle[7]. This was the first public establishment to provide coeducational education, integrating both females and males

The value of the pedagogical innovations of this establishment is widely recognised in educational literature, which generally appreciates educational integration as a fundamental value: female and male education, primary and secondary education, interdisciplinary approaches through project-based method, integration of school culture with daily life, active learning, and group work, among others.[8]

All these aspects, which we will see replicated in subsequent experimental projects, made this case a model to follow.

The architectural project for the Manuel de Salas Experimental High School was designed by La Sociedad Constructora de Establecimientos Educacionales (SCEE) (or Society for the Construction of Educational Establishments, as it would be known in English), under the direction of the architect, José Aracena. The construction plans for the complex were first approved in 1950, with completion occurring in phases over the years. It progressively incorporated the complex elements required for comprehensive education: sciences, arts and crafts, and physical activity.

Modernisation, in this case, considers functionality and hygiene but does not compromise on a modernising aesthetic. Instead, it followed the guidelines of the original residential building that initially housed the school, from the architects Smith and Solar.[9] Thus, the architecture maintained a palatial character for the entire complex, rich in ornamentation, with great attention to details such as moldings and finishes (**Fig. 1**).

Technical and construction innovations were also introduced. In 1952, the gymnasium building was designed, characterised by its large spans and reinforced concrete structures. Its basement also included sanitary facilities, changing rooms, and a significant area designated for a manual work workshop, to encourage vocational exploration.

The auditorium was also to have had a grand project dated that same year, but this was never built. Subsequently, the expansion of the laboratory building in 1961 provided specialised spaces for home economics and sewing education, as well as for the physics, chemistry, and biology laboratories, designed along similar lines to the previous project.

2.2. DARÍO SALAS EXPERIMENTAL HIGH SCHOOL

The Darío Salas Experimental High School was established in 1947 (Decree N. 1442) as a co-educational high school located in the southwestern sector of Santiago. The determination of its location was of vital importance for

experimental high schools, as the Gradual Renewal Plan for Secondary Education[10] that initiated it, sought to conduct pedagogical trials in social realities equivalent to those of other common high schools in the country, where the methods would be applied once properly tested and proven.[11] The first establishment was housed in a mansion in the *Estación Central* neighbourhood; however, it soon became necessary to design new facilities for its operation. This was not only due to the significant increase in student demand in the southwestern sector of Santiago but also because it became essential to have adequate spaces for the requirements of the experimental programme: guidance services, social assistance, medical and dental services, library, physics and chemistry laboratories, manual arts workshops, and home economics education, which the original mansion did not provide.[12]

The project for the new buildings was commissioned by the SCEE to architect Jorge Aguirre Silva, renowned for his extensive architectural work. The project, dated 1950 in its original proposal, featured isolated pavilions arranged in a comb-like layout without abandoning the more traditional organisation of the time, where the buildings form the walls of a compact block. On observing this, architect Alfredo Jünemann identifies it as a "transitional" school building,[13] as it anticipates the arrival of the comb-like buildings that would first characterise new private school complexes and at a later date also public schools and high schools, by a decade. The classroom pavilions have an open ground floor, increasing the courtyard area, given that the site is small in relation to the capacity of 1,000 students.[14]

The experimental architectural programme is evident in the allocation of certain buildings, which differ in their architectural form from the pavilions primarily intended for classrooms. An auditorium and gymnasium, featuring a double height building with an angular facade, were situated next to the school's entrance, facing the main avenue, providing it with an urban presence within the neighbourhood. Science laboratories and a manual practical workshop, with low buildings and skylights for illumination, were planned for the back of the site, although they were not constructed. Opposite the central courtyard, there was a four-story octagonal tower above a sunken courtyard. The ground floor housed the dining hall, and the upper floors contained classrooms for music and arts, with a terrace-patio for students on the top floor. This tower is unusual among school building typologies, awarding particular prominence to the artistic school programme (**fig. 2**).

2.3. GABRIELA MISTRAL EXPERIMENTAL HIGH SCHOOL

The Gabriela Mistral Experimental High School was established in 1946[15], as part of the same initiative for renewed high schools previously described. The main pedagogical coordinates proposed the active participation of the educational community, the implementation of educational methodologies oriented towards facilitating learning through active methods such as workshops, laboratories, projects, and group work, flexible classrooms, and correlated activities developed simultaneously throughout the high school.[16]

Bringing experimentation into the classrooms was active, participatory, and experiential. This is expressed, for example, at the class level through the establishment of previously non-existent Class Councils, including the election of Boards and Work Committees.[17]

The construction of new facilities, designed to respond to innovative educational proposals, was one of the dimensions that highlighted the experimental approach at that time. This was expressed in "an architecture that reflected the new social and technological processes of its era."[18] The architectural project for the Gabriela Mistral Experimental High School, undertaken by the SCEE under the direction of architect Juan Hidalgo, was approved in 1958[19] with the buildings completed in 1962 according to SCEE records.[20] Interestingly, its architecture did not gain visibility in architectural periodicals, making it virtually unknown in our context despite its significant attributes, which remain observable to this day. For its documentary reconstruction, our research relied on rarely circulated historical documents, such as SCEE reports, decrees, documents, and blueprints from public archives.

The school complex is composed of several isolated and interconnected pavilions within a large square site at the corner of two wide avenues. Two aspects stand out in the architecture of the high school: the experimental educational architectural programme and the formal autonomy of the architectural pieces that make up the complex. Regarding the architectural programme, similarly to the previously analysed high school, a significant area near the main entrance was allocated for medical, dental, and social assistance, a library, and vocational guidance services, all of which were central to the educational proposal.

The main pavilion housed theoretical classrooms on the second and third floors, including a geography classroom with an adjoining map room. In total, there were 30 classrooms, including a second two-floor pavilion. A distinctive feature was that on the first floor, the classrooms connected to an adjacent courtyard designated for outdoor classes.

Aside from the theoretical classroom pavilions, there was a third pavilion dedicated to practical learning, with workshops for manual labour, ceramics, and cardboard work, as well as a sewing room on the first floor. The second floor was dedicated to physics, biology, and chemistry. Each of these three areas consisted of exhibition rooms and laboratories equipped for direct student experimentation, serving as models for the appreciation of practical learning. The third level of the practical programme included a large drawing room.

The original project included the construction of an auditorium with seating for 500 people and a balcony for 450, adjacent to the main entrance building, forming a single continuous curve of the facade. This auditorium would have an independent entrance from the avenue, covered by a second marquee. Although this building was ultimately not constructed, leaving this flank of the main building unresolved, the imposing gymnasium was completed. Located in the centre and at the back of the complex, it was

20. Sociedad Constructora de Establecimientos Educacionales, *Veinticinco años* (1962).

surrounded by the open school courtyard. The gymnasium is notable for its slender wall structure and curved roof, as well as the transparency of its glass facades.

Another memorable space is the covered courtyard, which, among other uses served as a gymnasium and assembly hall and was equipped with a small stage at one end and connected to the dining halls at the other end under a vaulted roof supported by slender pillars. Although this space is barely recognisable today due to transformations of the building, it is clearly observed in the original blueprints. This area was particularly relevant and provided unity to the complex, not only because of its transparency and its role in connecting the various buildings but also due to its undulating roofs, which contrasted with the straight-line characteristic of the rest of the architecture (**Fig. 3**).

Historical photographs and technical specifications reveal that the use of colour was also a particularly prominent element here, as a significant portion of the glazed facades featured an intercalated pattern of blue and yellow, made of *'plastiglas'* (or plexiglass), mounted on the metal framework.

Another interesting aspect of the design was the integration of built-in carpentry and furniture, such as partitions that included doors, movable lattices to promote cross ventilation, and glazed surfaces for bilateral lighting, along with storage spaces for educational materials within the classrooms or offices. These elements, made with native wood carpentry, have been preserved to this day and exhibit high construction quality, making their conservation desirable, especially given the risk posed by careless renovation processes in contemporary school buildings.

3. ARCHITECTURE FOR EXPERIMENTAL SCHOOLING

In summary, the review of the presented cases highlights the following aspects:

First, the provision of a complex and extensive architectural programme aimed to balance, if not quantitatively then at least qualitatively, the place of practical education compared to the predominant theoretical teaching. The dedication to the design and equipment of laboratories and workshops for trades and/or the teaching of visual arts, music, and/or performing arts was prominent due to the architectural resources within the complex.

Second, the presence of an auditorium and gymnasium within the school programme gave the building a cultural presence within its neighbourhood. The use of auditoriums was not exclusive to experimental high schools but was also present in simpler school groups and other relevant urban complexes.

There is also a greater extension of the support programme associated with the administrative area: medical, dental, social, and vocational guidance facilities, that transformed the school from a selective establishment to a formative and orientational one.[21] These facilities, in addition to assisting students, were likely part of the scheme to gather scientific evidence regarding the functioning and pedagogical methods employed.

The original authors, as well as recent research, highlight the transnational nature of these modernisation processes in educational reforms that followed the second post-World War.[22]

Regarding the architectural form, the school displayed formal resources that evidenced markedly modernising forms: the transparency of interconnected spaces, the lightness and large spans of the structures in auditoriums, and even the use of colour on the facades.

It has also been possible to observe that, as is common in architecture, the arrival of new school buildings was delayed in relation to the period of educational experimentation between 1946-1965. In the cases of the Darío Salas High School and the Gabriela Mistral High School, our research detected long processing and execution times that raise doubts about the effectiveness and consistency between educational and architectural experimentation. Nevertheless, the analysis of the projects shows an architecture that firmly supported the conception of a modern school space, applied in sectors of Santiago's capital that for the first-time opened school complexes of such quality, complexity, and scale. ■

A CLASSROOM TO CHANGE THE WORLD: THE SCHOOL ARCHITECTURE OF THE MINISTRY OF PUBLIC WORKS OF URUGUAY (1954-1965)[1]

ALFREDO PELÁEZ IGLESIAS
FACULTAD DE ARQUITECTURA, DISEÑO Y URBANISMO,
UNIVERSIDAD DE LA REPÚBLICA, URUGUAY

ABSTRACT

Architects Hugo Rodríguez Juanotena and Gonzalo Rodríguez Orozco designed the *Comprehensive Classroom* for the Ministry of Public Works in the 1950s and the 1960s. It consolidated all the learning spaces that were dispersed, such as the workshop, laboratory, toilets, indoor and open-air classrooms and experimental garden, into a generously sized unit, shaping by repetition the whole school building, eliminating the need for corridors. Simultaneously, a curricular change in the Uruguayan Elementary Public School tried to incorporate the pedagogical ideas of the New School movement. In this context, the Comprehensive Classroom updated the concept of school architecture in the country. This paper focuses on analysing the interior space to demonstrate the ideas and strategies involved in this design in close relation with pedagogical thought. We argue that the Comprehensive Classroom represents a shift in spatial paradigm in the Public Elementary School in Uruguay, supported by modern architecture ethic and aesthetical values. It would attest to the political role of the architects and public work offices to promote innovative solutions and the design potential to influence in societal transformation. This paper also made use of critical and historical methods, consulting on original and unpublished documents with particular focus on graphic materials. The available information was complemented with drawings and images created by the author.

1. INTRODUCTION

Architects Hugo Rodríguez Juanotena (1923-2012) and Gonzalo Rodríguez Orozco (1930-2016) designed the *Comprehensive Classroom* for the Ministry of Public Works in the 1950s and the 1960s. The Comprehensive Classroom had different versions over time, but the main idea was to consolidate all the dispersed learning spaces, such as the workshop, laboratory, toilets, indoor and open-air classrooms and experimental garden, in a generously sized unit, shaping by repetition the whole school building, eliminating the need for corridors.

At the same time as a curricular change in the Uruguayan Public Elementary School that aimed to incorporate the pedagogical ideas of the New School movement, the Comprehensive Classroom updated the concept of school architecture in the country.[2] We can see how it attempts to move away from the traditional idea of the school space to another of a domestic nature, focused on children as the primary beneficiaries of education. The users have the possibility of transforming the setting and the interior space can be open towards the outdoors nearby and the city. Furthermore, we can appreciate the design of the school scenario to the extent that the techniques with which it was built were showcased as a model of beauty and behaviour.

Despite being valued at the time, the Comprehensive Classroom has not been sufficiently highlighted and studied by the academy. It was notably absent, for example, from the Uruguayan section of the exhibition on Latin American architecture at MoMA in 2015.[3] This invisibility is also appreciated in the fact that the constructed buildings with these units have not been properly preserved, having suffered from multiple alterations, which makes it difficult to recognise them directly.

This work aims to contribute to the field of architecture and the history of education by studying this high-quality experience of public works in Uruguay. This paper focuses on the interior space to illustrate the ideas and strategies involved in this design in close relation to pedagogical thought. We will argue that the Comprehensive Classroom offered a change of space paradigm in the Public Elementary School in Uruguay, supported by modern architecture ethics and aesthetical values. It would demonstrate the political role of the architects and the public work offices in promoting innovative solutions and the design potential to influence in societal transformation.

Understanding school settings as interfaces between people, objects, activities and the environment, influencing their bonds, movements or perceptions, we can observe how the design of the Comprehensive Classroom attempted to dialogue with the new curriculum and collaborate with the change of social and cultural traditional relations.[4] This transformation was based on the separation of the intellectual and the manual, the individual and the collective, the domestic and the institutional, the interior and the exterior. This dialogue between architects and teachers is not simple or linear, but rather it is a complex relationship involving a network of actors with mutual and sometimes contradictory influences. This makes the architectural project a critical instrument, in debate with institutions, society and culture.

1. This paper is based on the author's PhD thesis "El pizarrón móvil y la mesa colectiva. El Aula Integral del Ministerio de Obras Públicas de la República Oriental del Uruguay (1954-1973)", supported by CAP Udelar.

2. Consejo Nacional de Enseñanza Primaria y Normal. *Programa para escuelas urbanas aprobado por resolución del Consejo Nacional de Enseñanza Primaria y Normal de fecha 1° de marzo de 1957*. (Montevideo: Imprenta Nacional, 1969).

This experience presented a new perspective on the school building relationship system, and bringing it to the present could allow us to reflect critically on the current design practice of school architecture.

In order to achieve that, critical and historical methods were used. Original and unpublished documents were consulted with particular focus on graphic materials. The available information was complemented with drawings and images created by the author.

2. RENEWING SCHOOL ARCHITECTURE IN URUGUAY

School architecture in Uruguay by the middle of the twentieth century had primarily been constructed in response to the institution's pedagogical practices, which were based on individualised and intellectualised teaching rooted in Hebart's theories.[5] The public elementary school in Uruguay was well consolidated, providing free and compulsory education for children from 5 to 12 years old. The classrooms were directional and equipped with fixed benches, resembling an auditorium. There were two instances of experimental school buildings in the late 1920s, with a vocation for social transformation, but those were isolated cases.[6]

In the 1950s, the institution's renovation of teacher and school curriculums was the subject of debate. The debate focused on two different approaches to equipping and organising the classroom: using fixed benches or collective tables. These approaches were considered in terms of the interpersonal relationships they would allow.[7] The 1957 Programme incorporated innovations of pedagogues such as Jesualdo Sosa (1905-1982) or Clemente Estable (1894-1976), based on creative expression and scientific experimentation.[8] These innovations coexisted with the restrictions and institution's habits.

At the same time, the shortage of well-maintained buildings highlighted the urgency of carrying out a major school construction plan. However, there was no clear indication of the requirement for a new school space model that aligns with the new curriculum. In fact, this happened at the initiative of the Ministry architects, who integrated a differentiated system of relationships within the classroom into an economical, rational and easily implemented solution. Although several versions were designed (1956, 1958 and 1960), the Comprehensive Classroom can be considered a single project with variants.

This proactive attitude is framed in the context of the expansion of public works in the country during those years. This expansion was associated with modern architecture and a new generation of architects. It was accompanied by the radical reform of the Faculty of Architecture of Montevideo, where Rodríguez Juanotena and Rodríguez Orozco were both professors, with a policy that privileges the social contents of the curriculum and modern architecture as an instrument to bring about change.[9]

On the other hand, on an international level, there was a push to develop educational buildings based on the new teaching methods. This is reflected in Roth's work, where he emphasises the Anglo-American experience of the interwar and post-war periods. This period was

characterised by single-story linear pavilions and open-air classrooms, and Roth insisted on the value of designing school spaces to forge new forms of social coexistence.[10]

3. DIALOGUES BETWEEN ARCHITECTURE AND PEDAGOGY

In order to understand the teaching contribution of the Comprehensive Classroom and to establish links with the new school curriculum, we will analyse four key points: domesticity, activity, openness and intelligibility.

3.1. DOMESTICITY

The concept of the self-contained classroom involved using the area previously dedicated to the corridor as a pedagogical area, trying to minimise movement throughout the building by also allowing direct entry to the classrooms from the street. Eliminating the corridor, on the one hand, aimed to reduce the disciplinary issues associated with traditional corridor behaviours (where the students were made to form lines), in contrast to other contemporary cases where the corridor was conceived as a didactic device.[11] On the other hand, it sought to protect students from situations that could lead to "*promiscuity*" by moving to the toilets away from adult supervision while granting them autonomy for their use inside the classroom.[12]

Here we can see how the idea was to promote children's sense of self-determination, to develop their creative and intellectual potential, releasing them from an institutionalised space to a more familiar one, with more subtle supervision.[13] The classroom was conceived as a home, focusing education on children, providing them with the elements to be able to "*live a full physical, mental and emotional life"*.[14]

3.2. ACTIVITY

This strategy allowed for an increase in surface area, forming a single bilaterally illuminated and ventilated volume (8x10-9m). It collaborated in the interior spatial isotropy, allowing greater versatility in its occupation with light furniture units. There were fixed countertops for workshop or laboratory work to the south, while to the north, separated by a cabinet, there was a classroom with movable blackboard partitions on its sides.

This organisation appears to have responded to the new curriculum's experimentation and expression by providing specific furniture and spaces for these purposes. These activities were usually segregated in the building, reflecting a fragmentary structure of knowledge, which separates the manual from the intellectual.

On the other hand, the curriculum gave the teacher the ability to administer didactic techniques with flexibility, depending on the observation of children and their environment.[15] Here the generous dimensions of the classroom and the possibility of moving its blackboard side partitions to bring units together allowed for a wide variety of configurations, bringing it closer to open-space school configurations. However, we know that traditional benches were used to occupy these classrooms, limiting their

capacity for transformation.[16] The exception was the first year's classrooms, where collective tables were used. This juxtaposition of a traditional school organisation on a setting that aims to renew it is understood as a way of cushioning a change perhaps seen as too radical by the teachers.

3.3. OPENNESS

The school programme proposed a correlation between expression and experimentation, linking them with outdoor life. If the exploration of the world were approached according to the experimental method, the knowledge of the human body would also be emotionally approached. This involved children expressing themselves through "*teaching by rhythm*", dances, games and music, which had their privileged place outdoors.[17]

The classroom extroversion was underlined by the possibility of open-air teaching, moving the blackboards, or working in the experimental garden adjacent to the outdoor classroom in the first version. This allowed for a seamless visual and physical connection from the interior to the exterior, aligning with the curriculum's objectives.

In this sense, the school design consists of several volumes positioned in a linear and horizontal formation, with a maximum of 6 units, in addition to an administrative pavilion. These buildings were dispersed and parallel to each other, connected by open galleries. This arrangement made the school similar to a park, where the outdoor spaces, rather than being hidden, were exposed and interacted with the urban environment.

3.4. INTELLIGIBILITY

The good, the beautiful and the true were identified in the school, bringing together moral formation with the love for beauty and culture. This went beyond teaching aesthetic education to the cultivation of ethical values.[18] Thus, a genuine and stimulating environment was required, with art and architecture as a model of behaviour.[19]

The realisation of the art murals at the entrance to the school was carried out independently from the classroom unit, with limited collaboration with artists. In contrast, the intelligibility and technical integrity of the school scenario are explicitly sought after. The construction was prefabricated based on panels and metal frames; later, due to the economic crisis, the project moved to reinforced concrete and apparent masonry, moving away from the expectations of building industrialisation. The roofs consisted of lightweight reinforced beams showing the structural stresses in their form. In this way, the intelligibility of the construction exceeded the strict technical necessities, giving it a flexible, didactic value.

4. AFTERWORD

The Comprehensive Classroom was ambiguously accepted and implemented by the school institution, despite its convergence with the new curriculum. Criticism received for its renovating ambition and supposed lack of articulation with teachers led to the discontinuation of the project by mid-1960s.[20]

The Comprehensive Classroom stressed the relationship between architects and teachers. It involved a political proposal, a re-description of reality in order to transform it, based on a particular idea of childhood and teaching, where the aesthetic, often undervalued, acquires a privileged role. It not only meant a radical overhaul of traditional routines, but also a distinct repositioning of knowledge and interpersonal relationships in society. ■

ADAPTIVE REUSE AND SUSTAINABLE CONSERVATION FOR MODERN EDUCATIONAL ARCHITECTURE

ZAINAB MURTADHAWI
KUWAIT INSTITUTE FOR SCIENTIFIC RESEARCH

ULA MERIE
UNIVERSITY OF BABYLON

ABSTRACT

Adaptive reuse is a complex process that aims to preserve the values of heritage buildings while adapting them for present use and transferring them to the future. With the rise of carbon reduction campaigns driven by the climate emergency, adaptive reuse has gained more traction as an alternative to demolishing and replacing older buildings. It is now generally seen as a crucial component of sustainable practice strategies. Thus, most old buildings necessitate modifications and ingenuity to regain functionality and generate a renewed appreciation for their historical, architectural, and socio-economic significance.

This discussion may be reframed in modern educational architecture to include contributions from aspects beyond its functional adaptation. It is posing additional issues considering the changes brought about by the 21st-century's technological advancements, educational methods, and pedagogical objectives. Modern educational architecture has been specifically developed to prioritise modern architecture's functionalist and rationalist principles. School buildings and university campuses have been deliberately designed to conform to a particular set of structures, standards, components, and classifications that embody the educational principles and methods developed in the nineteenth and twentieth centuries.

Given the constant shifts in teaching methods, climate conditions, spatial demands, and technological advancements that occurred in the 21st century, there is a need to examine the challenges and limitations modern educational architecture faces. These concerns must be addressed to improve the functionality of modern educational architecture, draw attention to it and emphasise its significance, cultural value, and preservation tactics. This paper sheds light on these challenges that require further spatial modification to the physical layout, climatic change and sustainability standards that demand a higher quality indoor environment, the assimilation of educational buildings into their urban and community contexts, and the recognition of historical value and heritage preservation.

1. INTRODUCTION

Educational architecture, created a new school layout typology that has been extensively used worldwide.[1] New teaching approaches and improved pedagogy were reflected in school building layouts, which changed learning settings from one room to linear classrooms.[2] With the development of nations' social services, these classrooms provided teaching and activities that followed the United Nations Educational, Scientific and Cultural Organisation's (UNESCO) pedagogical requirements.[3] Modern Architecture introduced the functionalist approach, which was crucial to rationality, at the same time as this sort of school building Hille.[4] More than 120 modern schools were used in Hille's book to illustrate society's social and economic requirements, ecological restrictions, and material growth. This purpose-built educational architecture is still in use. Its status is valuable for educational purposes, as well as for presenting a significant contribution to architectural history.

The decaying architecture of schools lacks the physical requirements for contemporary learning. Its spaces are inadequate for 21st-century schooling.[5] Modern educational architecture met teaching methods and created functional spaces with environmental considerations like natural light, cross ventilation, and friendliness, but climate change and innovative pedagogical approaches require further changes.[6]

From a historical standpoint, several of these modern educational buildings have had a notable influence on cultural and social norms.[7] These landmarks not only served as physical symbols but also played a role in providing for the nation's welfare, transmitting social and political demands, and contributing to its modern historical development. This emphasises the significance of modern educational architecture as a physical space for learning, as well as a place where both tangible and intangible values are manifested. Thus, the crucial issue to address in this paper is which conservation strategies should be undertaken for historic or heritage school buildings to align them with the demands of the present-day education system while ensuring their authenticity and incorporating modern values to create adequate new learning environments.

2. ADAPTIVE REUSE CONCEPT

One of the most popular preservation strategies, adaptive reuse, finds a new use for an existing historic building, ensuring it will be around for the foreseeable future. According to Plevoets and Cleempoel, the concepts of adaptation and reuse form the basis of adaptive reuse.[8] They explained that modifications involving both functional and physical components are specifically mentioned by the word. This permits functional alterations to the building while preserving its historically significant elements. As a result of repurposing an old building rather than constructing a new one, less strain is placed on the planet's resources, which is why preservation and sustainability are synonymous.[9]

Adaptive reuse for heritage buildings is a method of managing cultural heritage sites and introducing new significance to an existing culture.[10] This

implies that the existing structure possesses both historical significance and architectural relevance. Hence, the extent of adaptation remains unspecified, encompassing a spectrum that spans from substantial modifications to the building's exterior to minor alterations confined to the interior.[11] While the first impact may not be immediately apparent, the change in purpose will ultimately result in substantial alteration. Certain buildings constructed throughout the modern age, such as educational institutions, continue to serve their original purposes, while others undergo significant transformations. Due to their outdated design, limited functionality, and inability to handle the rapid information exchange needed in the digital age, they often fail to meet contemporary needs.

The fundamental principles of adaptive reuse practice for historic buildings, according to Plevoets and Cleempoel, include authenticity, aesthetic appeal, and the age of the building.[12] According to Burke and Grosvenor, school's intrinsic feeling of shared memory, the palpable impact they have on the constructed surroundings, and essential historical relevance make them highly respected.[13] Therefore, it is important to conserve these buildings for their practical role as educational spaces, and their historical and cultural relevance, which have outlived their original purpose.

On the other hand, sustainability has been a highly discussed subject in the realm of architecture and urban planning during the past decade. Li et al. stated that scientific frameworks, procedures, and approaches should be used to guide adaptive reuse because the concept is oriented towards sustainability.[14] One part of sustainable ecosystems is making creative use of existing building stock. Contributing to sustainable architecture and cities are sustainable adaptations of cultural heritage. Because of the various moving parts involved in an integrated strategy, adaptive reuse of historic structures is not an easy task. According to Vardopoulos et al., adaptive reuse is a method for improving urban sustainability that helps with resource management, boosting the economy, making a place more appealing to tourists, and getting people involved again.[15] That is why adaptive reuse tools for sustainable conservation must get creative and develop new ways of thinking about and repurposing old buildings.

3. CONTEMPORARY CHALLENGES

Considering the preceding discourse, modern school architecture was established to unite pedagogical theories with modern architectural concepts. The concept of contemporary adoption and reuse of these buildings emphasises the potential of the educational environment to support learning processes and activities in schools. It is considered that these educational spaces are not only a representation of modern tangible heritage but also the intangible relationship between the education process and the social-cultural context. However, it could be argued that within this context, various actors and stakeholders, whether in educational policy or urban planning, should work to manage and share the responsibility of maintaining the conditions of education spaces while questioning the potential functions that could be re-adopted within these places. Considering this, it is essential to highlight

the main contemporary dimensions that were identified as the challenging factors of the adaptive reuse of educational spaces.

3.1. SPATIAL ORGANISATION AND PEDAGOGY

The spatial layout of the education environment and how this environment interacts with teaching and pedagogy play a significant role in activating knowledge gaining. Because the traditional pedagogical process, depends on positioning the teacher within the educational space, the spatial organization (space and place) of this institution was used to apply a systematic layout and urban structure that responded to the education process.[16] Yet, during the last decade, significant educational and technological development has impacted and challenged the traditional educational approach, where these spaces became inadequate and isolated from the development of pedagogical practices. Thus, in some cases, such as Al-Qayrawan School in Kuwait (as shown in Fig. 1), these spaces work to align and re-position their spaces and places to meet the new learning environment needs. This pushes toward seeking various layers of interactions and adapting the current spatial configurations to respond to the pedagogical challenges.

The case of the library building of Alvar Alto University (shown in Figures 2 and 3), was restored and reshaped in 2017 to house a media space that matches the individual and the group study's working needs. This offers a new perspective to understand the spatial organization of the modernist building and take its architecture to the twentieth century while introducing a contemporary notion of the social and cultural context. Yet, spatial adaptation may encounter different challenges associated with the fragile architectural details and the limited adaptive techniques that could be applied due to the building's status whether as a listed building or due to the cultural identity of buildings within its context.

3.2. CLIMATE CHANGE AND SUSTAINABILITY VISION

The adaptive reuse of existing educational spaces and buildings is a sustainable mechanism to give new opportunities to existing modernist buildings. As a strategy, it aims to prolong the life span of the existing educational spaces that are neglected, to achieve environmental, economic, or social heritage benefits, and to prevent these buildings at the level of demolished.[17] This strategy has been adopted widely across different functions, yet it requires that the building hold unique architectural details, cultural and heritage values within its context. Bearing this in mind, it should also satisfy the social expectations of the new targeted users and promote economic values.

According to Othman and Elsaay, sustainable principles are achieved by achieving the required functions that understand and match the users' and stakeholders' perspectives, desires, needs, and expectations while considering protecting the environment, enhancing society, and prospering the economy.[18] Therefore, the adaptive reuse of modern educational spaces will contribute and promote the different pillars of sustainability; through re-enhancing the social interaction with the community heritage, providing

an opportunity to celebrate the local materials and architectural values, in addition to reducing the unnecessary cost of structuring new buildings.[19]

3.3. URBAN AND SOCIETAL ASSIMILATION

The post-war period was generally considered the perfect chapter to embrace modern architecture in the education environment, where the spatial and urban design principles were experiencing different levels of transformations and challenges associated with the significant and rapid changes that the education policy faced. This period provides extraordinary proposals and opportunities in the way that the academic environment and its education policies reflect and express modern architecture. Mobilising technical capability, new structures, and materials intended to reflect these new innovative approaches. Within this, additional debate was raised towards understanding how this innovative environment could promote the meaning of its context, place, and nation. Bearing in mind achieving smooth transactions that would adopt the rapid changes in contemporary architecture and still reflect the individuality of its society.

To understand that Maurrasse suggests specific aspects that can help and support the local community engagement in the possess of connecting the education environment and the city.[20] First the scale of the education environment as an institution, the level and the degree of the relationship between the institution and its context, the capacity and the potential of the community–based institutions, the history the culture dimensions and structure, the financial support, or funds of the institution, and finally, the education environment, its mission and commitment towards both its context and institutional innovation. These aspects are suggested to enhance the educational space and improve the urban quality of its community. Thus, we should acknowledge that there is a clear interaction between the adopted education policy and the perception of its spatial design unity and integration within its context.[21]

During the last decades, educational spaces, such as classrooms, libraries, laboratories, and halls were the perfect platform to validate the quality of architecture and share the responsibility towards achieving social spatial justice. Pedagogy place's main aim is to generate an intellectual place that has its character and identity within a collaborative safe environment. Yet, determining the borders of this relationship could vary according to the social-cultural norms, the historical context, and the education policy which might be gradually shifted or altered across time. Thus, adapting this space should emphasize the potential of the place as a vital aspect of adaptive reuse policy, and its identity within its context and surrounding environment.

3.4. HISTORICAL VALUES AND HERITAGE PRESERVATION

Adaptive reuse as a strategy is focused on reviving the educational spaces of modern architecture which are considered as a modern heritage. This helps to revive the cultural identity, preserve the architectural value of educational places, enhance cultural authenticity, and promote spatial justice.[22]

19. Ezzat Othman and Elsaay, "Adaptive Reuse: An Innovative Approach for Generating Sustainable Values for Historic Buildings in Developing Countries".

20. David J. Maurrasse, *Beyond the Campus How Colleges and Universities Form Partnerships with Their Communities* (New York and London: Routledge, 2001).

21. Maurrasse, *Beyond the Campus How Colleges and Universities Form Partnerships with Their Communities*.

22. Plevoets and Cleempoel, *Adaptive Reuse of the Built Heritage Concepts and Cases of an Emerging Discipline*.

The historical values of the heritage building are an integral part of the national pride. Adaptive reuse can offer new ways to access heritage buildings in addition to transforming their surrounding context. It opens the way towards achieving self-sufficient funding, new functions, and utilising heritage preservation according to the new image of the building. Yet, this strategy requires special attention to the structural integrity and building codes, and whether these codes meet the safety measures or not.

4. EXCHANGING CONSTRUCTIVE STRATEGIES

For sustainable conservation and adaptive reuse implementation principles, it is necessary to examine each case from various regions. Even though modern educational architecture shares similarities in its principles of design and standards, it differs from one region to another. Kindergartens, primary, intermediate, secondary, and universities all serve the purpose of education; however, they differ in terms of the designer, materials and technology used, the region, climate, pedagogical requirements, and the age and gender of the students. Additionally, buildings have undergone modifications over time because of the various policies and guidelines that have revealed distinct alterations in each instance. Consequently, adopting adaptive re-use practices in each instance broadens our comprehension, enabling the exchange of knowledge and expertise across national and cultural boundaries.

5. CONCLUSION

Adaptive reuse is a thrilling and dynamic method of progress that can creatively reach multiple significant historical, cultural, economic, and environmental objectives. This study provides further reasons to support the expansion of the adaptive use of historical buildings from the standpoint of modern educational architecture. In this article, schools and universities exemplify modern architecture that addresses the challenge of modernisation while preserving its original purpose. It examines the present challenges related to physical use, environmental aspects, integration into urban areas, and the significance of educational spaces in terms of their legacy. Its objective is to bring up new subjects that can impact the implementation of sustainable conservation and the adaptive repurposing of such spaces.

This inquiry has examined adaptive reuse in a manner that should prompt future investigation into this rising phenomenon. We need new foundations for innovative and sustainable design. This understanding would also help preservation professionals negotiate with project stakeholders and government authorities to balance preservation, adaptation, functioning, and budget. We wanted to show that adaptive reuse can be seen as a process rather than just an architectural design intervention, which might help establish a complete and dynamic approach to adaptive reuse. It is widely supported as a sustainable technique. It is essential to weigh each facility's pros and cons of adaptive reuse.

The paper has brought several general concerns about assessment approaches, pedagogical and climate change requirements, and adaptive

reuse practice methods. At the 18th International DoCoMo Mo Conference, discussions around the role of adaptive reuse in creating a more sustainable educational built environment will reveal treatment techniques that involve preserving, rehabilitating, restoring, and reconstructing educational architecture worldwide. This presents an excellent chance for conservators to collaborate and share their knowledge, theories, methods, and requirements to achieve a unified and significant outcome that caters to a diverse range of expertise. ■

BIOGRAPHY

Zainab Murtadhawi obtained a PhD in Modernist and Welfare Architecture from Sheffield School of Architecture and an MSc in Sustainable Building Conservation from Cardiff University in the United Kingdom. Her thesis focuses on the modern educational architecture in Kuwait, specifically in relation to the period of modernisation that occurred after the discovery of oil. She is an Associate Researcher in the Construction and Building Materials Programme at the Kuwait Institute for Scientific Research (KISR). Her research focuses on Modern Architecture in the Middle East, with a particular emphasis on the repurposing of Welfare Architecture in the built environment.

Ula Merie holds a PhD from Sheffield School of Architecture in the UK. She is a researcher at Heritage Borders of Engagement Network/NTU, a representative for Iraq in the Epidemic Urbanism Initiative, a Research Fellow of The Academic Research Institute in Iraq (TARII), an Associate at the GIGA Institute for Middle East Studies, and a visiting lecturer and external examiner at the University of Baghdad, Iraq. Her research focuses on history and theory of architecture in post-war cities, spatial justice, conflicted identity(s), politics, ethics and gender equality, and the contestation of urban environments-between public and private.

REPURPOSING MODERN HERITAGE SCHOOLS IN KUWAIT: A FRAMEWORK FOR ADAPTIVE REUSE

#05

RABAB RAES KAZEM
NATIONAL COUNCIL FOR CULTURE, ART AND LITERATURE

NASER ASHOUR
NATIONAL COUNCIL FOR CULTURE, ART AND LITERATURE

ABSTRACT

This study explores adaptive reuse techniques for preserving cultural buildings, with a particular focus on modern heritage schools transformed into structures with new functions. Balancing a case-by-case methodology with a semi-universal approach for Kuwait, the research advocates for a nuanced exploration through a comprehensive case study, considering the evolution of educational pedagogy. A central inquiry revolves around determining what elements should be preserved, altered, expanded, and modified architecturally. The primary emphasis is on the spatial layout, architectural elements, and programme distribution within the chosen context. The distinctive tectonic form and programme relationship emerge as pivotal aspects that distinguish the building as inherently modern in comparison to Kuwaiti vernacular architecture. The empirical facet of this research unfolds through an experiment conducted at the Adailiya Campus for the College of Architecture. Initially a kindergarten school, the campus underwent a transformative renovation in 2019 to house Kuwait University's College of Architecture. This renovation not only reshaped the physical structure but also redefined its functionality by introducing additional structures to support studio spaces for architecture students, later expanding to accommodate the Interior Architecture department. The Adailiya Campus exemplifies how modern heritage structures can be repurposed to meet contemporary educational needs, providing insights into challenges and opportunities inherent in adapting schools into renewed structures. In summary, this study contributes to the discourse on preserving cultural buildings by providing a nuanced understanding of adaptive reuse techniques within the context of educational spaces evolving into modern heritage structures. The findings aim to inform architectural practices, heritage conservation strategies, and educational policies, striking a delicate balance between preserving historical essence and addressing contemporary and future needs.

1. INTRODUCTION

Traditional education in Kuwait was primarily conducted within the confines of mosques and private residences, where scholars imparted religious teachings and basic literacy skills[1]. However, the modernisation and formalisation of education began in the early 20th century, spurred by Kuwait's burgeoning oil wealth and a growing desire for social progress. The government established the first formal school, Al Mubarakiya School, in 1911, marking a significant milestone in the country's educational journey[2]. Subsequent decades saw the establishment of more schools, both public and private, catering to the diverse needs of Kuwaiti society. Today, Kuwait boasts a robust education system that emphasises both traditional Islamic values and modern academic disciplines, with a strong emphasis on literacy, numeracy, and technological proficiency. Kuwait has a history of demolishing modern heritage schools that have become obsolete and forgotten, viewed as eyesores needing removal. To reduce this trend of demolition, we propose the adaptive reuse method. These schools are emblematic of Kuwait's post-oil era, a time when education flourished and architecture symbolised the nation's prosperity. They represent modern heritage in terms of architecture, economy, and society.

2. HISTORICAL CONTEXT AND ARCHITECTURAL ANALYSIS

In the early 20th century, Kuwait lacked a formal educational system, with only a few Quranic schools, called Al-Katatib, funded privately, providing basic education. The establishment of Al Mubarakiya School in 1911 marked the advent of modern education in Kuwait, catering to commercial and clerical training. Subsequent developments included the founding of Al-Ahmedia School in 1921, offering English courses, and an all-girls school providing education in Arabic, home economics, and Islamic Studies. Government involvement in formal education began in 1936, leading to the proliferation of schools, with 17 established by 1945[3].

3. OVERVIEW OF KUWAITI VERNACULAR ARCHITECTURE

Kuwaiti vernacular architecture, rooted in history, culture, and climate, reflects a nomadic lifestyle adapted to the desert. Key features include the iconic "bâdgir / ريق داب" for natural ventilation, mud-brick walls, and enclosed courtyards for cooling and privacy. Ornate details like mashrabiya screens and geometric patterns highlight Kuwaiti craftsmanship and cultural motifs. Despite modernisation, efforts to preserve and integrate traditional elements persist, honouring the country's cultural heritage amid contemporary developments.

3.1. AL-QIBLIYA SCHOOL

The Al-Qibliya School, originally belonging to Mr. Khalaf Al Naqeeb, underwent a transformation into a school in 1938. It is unclear whether the building was given or bought for this purpose. Initially, it was a girls' school constructed with one storey only, using the only available construction method at the time: mud construction. In the 1950s, a second storey was added to accommodate more classes, further expanding the school.

3. History of Education in Kuwait, (تاريخ التعليم في الكويت الابتدائية والكويت), (Ministry of Education Kuwait), accessed April 2024, https://moe.edu.kw/pages/history

The circulation consists of a "liwan" with columns supporting the roof, serving as a transition for the classes and facing towards the interior.

Following the acquisition of the building by the National Council of Culture, Arts, and Literature, adaptive reuse was implemented. The new function of the building is as a cultural centre, housing offices for the engineering department and other amenities.

Traditional rows facing the teacher have given way to adaptable spaces supporting collaboration, creativity, and experiential learning. Today's designs prioritise natural light, ventilation, and outdoor access for student well-being and engagement. Open floor plans, flexible furniture, and integrated technology facilitate dynamic interactions, promoting holistic learning experiences.

3.2. TRIPE AND WAKEHAM

As Kuwait's education system evolved, so did its architectural landscape. The concept of the Kuwaiti courtyard house, with its emphasis on privacy, natural ventilation, and communal living, influenced the design of modern schools. Courtyards, reminiscent of traditional Kuwaiti architecture, became central features in school designs, providing open spaces for students to gather, socialise, and engage in outdoor activities. Additionally, modern schools incorporate elements such as shaded walkways, natural lighting, and passive cooling techniques to mitigate the effects of the region's harsh climate. By integrating traditional architectural elements with contemporary educational needs, Kuwaiti schools exemplify a harmonious fusion of cultural heritage and modern functionality.

The main spaces were oriented to the northeast, with balconies and cantilevers facing southeast, often shielded by louvers and screens. Faced with a shortage of local labour and suitable materials on site, the architects standardised concrete elements such as beams, floor panels, and column sizes, implementing them in a regular three-metre grid. They used Amara blocks for wall panelling to address these challenges[4]. This design concept features a two-storey, open-air layout, with classroom wings separated by hallways, allowing for greater cross ventilation and making good use of natural light. (**Fig. 1**)

3.3. ALFRED ROTH

Alfred Roth, a Swiss architect renowned for his expertise in school buildings, was recommended by English architect Leslie Martin, who at the time served as a consultant for the Ministry of Public Works. He was invited to Kuwait in September 1965. During Roth's visit to the Kuwaiti schools designed by German and English architects, he identified deficiencies, particularly a disregard for climate conditions[5]. He observed that the classrooms and buildings were excessively open to the environment, which consisted of vegetation-devoid sand. The long and narrow classrooms were also noted as unsuitable for the climate. Roth also argued that the buildings used more area than necessary in circulation and open spaces, possessed inefficient sun and acoustic control, were absent of anthropometric standards, and had no

Roberto Fabbri, "Prototyping Spaces for Education Pedagogy, School Planning, Standardization, and Prefabrication in Kuwait's Drive to Modernity.", in *Essays, Arguments & Interviews on Modern Architecture Kuwait, 1949-1989*, ed. R. Camacho, S. Saragoça and R. Fabbri (Zurich: Niggli, 2017), 45-60.

architectural quality. Consequently, Roth submitted a detailed report of his criticisms and suggestions, along with a sketch, by the end of his visit. One of Roth's main beliefs was that the school acts as an extension of a traditional Kuwaiti courtyard house[6].

3.4. AL RUMAITHIYA SECONDARY SCHOOL

Alfred Roth's ground-breaking endeavour, the Rumaithiya Secondary School now known as Al Qayrawan Middle School for Girls, broke ground in 1967 and reached completion in 1971 (**Fig. 2**). Conceived as a response to existing school designs by German and English architects, Roth's prototype echoed the traditional courtyard layout, featuring a central courtyard with rooms opening inward and closed off from the exterior perimeter. The comprehensive space programme included classrooms, special rooms, faculty accommodations, a multi-purpose hall, and a gymnasium. Roth collaborated with the Kuwaiti Engineers Office (KEO) on construction, pioneering a design where all classrooms faced the central courtyard—a novel approach at the time.

The main building, spanning two storeys, housed special classrooms on the ground level, typically larger than average. The first floor accommodated twenty-one classrooms of smaller dimensions, accessible via a transition space positioned 85 cm below, ensuring smooth circulation. Vertical and horizontal window slits on the exterior walls provided protection against the intense Kuwaiti sun, complemented by glass bricks on the ground floor. Departing from predecessors, the building boasted a load-bearing structure of unplastered reinforced concrete. Outer walls made of white sand-lime bricks were insulated with plastered hollow blocks. Aluminium-framed windows and cast stone slabs covered the floors. Due to financial constraints, air-conditioning was omitted, replaced by Roth's innovative cross ventilation system, ensuring comfortable indoor conditions[7].

While the school is still in use, functioning as a school, the abandoned part of the site will be addressed for the framework. The site hosts buildings that used to be the faculty dormitory, then was repurposed as faculty offices. Now abandoned, the building consisting of two identical structures, sit on neglected land adjacent to the school property exposed to the elements, withering away.

4. ADAPTIVE REUSE AND ITS SIGNIFICANCE IN PRESERVING CULTURAL BUILDINGS

Adaptive reuse is a rigorous process, partly due to the cultural significance of these buildings and the number of stakeholders involved. Numerous studies aim to preserve the essential qualities and values of heritage sites, particularly schools, to enhance their current usability and ensure their future preservation. Preserving cultural buildings through adaptive reuse not only maintains a tangible connection to the past but also enriches community life by providing spaces for social interaction, education, and cultural activities[8].

Before these schools were abandoned, they underwent various transformations to accommodate changes and the increasing student population. Unfortunately, some of these changes, along with building

6. Alfred Roth, *Das Neue Schulhaus/The New Schoolhouse/ La Nouvelle Ecole* (Zurich: Girsberger, 1950).

7. Ricardo Camacho, Sara Saragoça, and Roberto Fabbri, *Essays, Arguments & Interviews on Modern Architecture Kuwait, 1949-1989* (Zurich: Niggli, 2017).

maintenance, were poorly executed, ultimately leading to their abandonment. The process begins with an analysis of the existing building, encompassing its historical, spatial, and technical aspects. This involves mapping out the building's evolution, gathering information about the site, materials, construction type, architectural elements, and surroundings. The findings from this analysis, investigation, and research are crucial for informing the architects' initial designs.

4.1. OPERATIONAL SYSTEM

In directing this process, it is essential to distinguish between recognised and categorised values in the value assessment. This enables the determination of the most significant elements deserving conservation. This inevitably involves decisions between conservation and change, blending and contrast, and continuity and partial renewal. However, it falls upon the architect to unify, balance, and fortify both the historic values and future functionality, alongside other pertinent values.

Once the appropriate function is determined and agreed upon for the building, various strategies can be implemented. Seven different approaches, depending on analysis, can be used when adding new elements to the building. These include:

1. Building within
2. Building over
3. Building alongside
4. Building around
5. Adapting to a new function
6. Building in the style of
7. Salvaging materials for recycling

4.2. CRITERIA FOR ADAPTIVE REUSE APPLICATION

In the process of repurposing old or historic buildings for new uses while retaining their heritage value; The criteria for an adaptive reuse application typically include the following considerations:

1. Historical Significance: Evaluate the building's historical value, considering architectural style, past events, and its contribution to heritage.
2. Structural Integrity: Assess the building's condition for safety and stability, determining if renovations are necessary.
3. Architectural Features: Identify and preserve key architectural elements that define the building's character.
4. Adaptive Potential: Evaluate the feasibility of adapting the building for a new use while maintaining historical integrity and modern functionality.
5. Market Demand: Analyse demand for the proposed space based on location, demographics, and economic trends.
6. Regulatory Considerations: Ensure compliance with zoning laws, building codes, and preservation regulations.
7. Financial Feasibility: Conduct a cost-benefit analysis comparing

8. Jorge Otero-Pailos, Thordis Arrhenius, and Erik Fenstad Langdalen, *Experimental Preservation* (New York: Routledge, 2022).

adaptive reuse to other options, considering renovation costs and potential income.

8. Community Engagement: Involve stakeholders to align the project with community values and priorities.

4.3. HISTORIC ASSESSMENT AND EVALUATION

As a start, the initial step in determining a conservation plan involves a comprehensive process of examining and analysing a historic building to understand its value, condition, and potential for adaptive reuse or preservation. This includes evaluating several key factors:

1. Age of fabric/style: Refers to the historical period during which the building was constructed and its architectural style. Understanding the age and style helps in determining its historical and architectural significance.

2. Condition: Pertains to the current state of the building's physical condition, including any structural issues, decay, or damage. Evaluators assess the level of deterioration and required maintenance or restoration efforts.

3. Utility: present/future: Evaluates the building's current and potential future usefulness or functionality. It considers whether the building is currently serving a purpose and its adaptability for future uses or renovations.

4. Importance in urban setting: Assesses the significance of the building within its urban context. Factors may include its role in defining the neighbourhood's character, its contribution to local history, or its influence on surrounding architecture.

5. Contribution to urban character: Examines how the building adds to the overall aesthetic and cultural ambiance of its urban environment. It considers architectural features, scale, materials, and historical context.

6. Details/artefacts: Refers to specific architectural details, decorative elements, or historical artefacts within or associated with the building. Evaluators assess their significance in preserving the building's historical or cultural value.

7. Archaeological/historical significance: Evaluates the building's importance from an archaeological or historical perspective. It considers any archaeological findings associated with the building or its site, as well as its historical relevance to the local community or broader historical narrative.

8. Loss of features: Refers to any original or significant features of the building that have been lost or compromised over time. This could include alterations, demolitions, or deterioration that have affected the building's historical integrity.

9. Unsuitable additions: Involves assessing any modern additions or alterations that are incompatible with the building's original design, architectural style, or historical significance. These additions may detract from the building's overall value or character.

5. FRAMEWORK

An Adaptive Reuse Framework was developed and designed to be adaptable, focusing on repurposing school buildings. Three different school prototypes

were selected, and the framework was applied to each, resulting in distinct outcomes for each case.

5.1. THE ADAILIYA CAMPUS

The Adailiya Campus presents a unique case, characterised by its evolutionary history and the blend of educational buildings added over time. Initially, it follows the "E" layout prototype, designed by A. R. Fuchs, a German architect at the Ministry of Public Works in the 1950s. Dubbed "Fox's Model," it features three levels. The main horizontal bar serves as the core, with three smaller bars extending from it. A narrow yet spacious transition space leads to larger classrooms or seminar halls. The initial prototypes of post-oil era schools were generously spacious, with significant amounts of unused space serving as corridors or transition areas. These spaces now offer the opportunity and flexibility to introduce appropriate interventions that enhance both the space and the functionality of the building. The smaller bars branching from the main one contain smaller classrooms, each flanked by exterior hallways. (**Fig. 3**)

5.2. IDENTIFY RENOVATIONS ON SITE

Fuchs's model was renovated only on the ground and first floors, leaving the second floor with little to no intervention. The old window frames were replaced with newer aluminium frames for better insulation. Doors were painted, and some were replaced. Large classrooms were redivided with gypsum board to accommodate the sizes according to the needs of the previous use. Access to the back corridors was closed off, leaving them unused.

The renovation of the Kindergarten consists of white Alucobond aluminium cladding on the exterior. A steel structure was added on the interior for support. Some repairs and additions to the site are not appropriate and need to be reconsidered to achieve better functional performance.

5.3. ASSESS AND ANALYSE

The first step in introducing a new use for a building is understanding it, exploring its features, and identifying new opportunities that would encourage people to use it. The more people use the building, the longer it remains vibrant, avoiding abandonment and deterioration.

5.4. INTERVENING WITH THE SITE

Introducing a new function to the site/building to host craft workspaces, small office spaces for local architecture firms offering internship programmes for training, and a section for an architect residency programme. The new function would also include a commercial section offering materials and art supplies, as well as a café and restaurant to generate funds for repairs and maintenance of the building. A facility management plan will be implemented before, during, and after the renovation to ensure the longevity of the building's function, allowing for flexibility to adjust to the needs of students and other users of the building.

The top floor of the building, currently abandoned, will host the three to four new functions after the necessary renovations and repairs. Each function/programme will be situated in one of the four wings.

Introducing the new functions programme:

1. Vocational crafts school
    a) Materials lab
    b) Lecture rooms and classrooms
2. Architect residency
    a) Communal studio
    b) Private office
    c) Meeting room
    d) Video streaming room
3. Commercial and offices
    a) Offices for rent
    b) Café
    c) Restaurant
    d) Communal working spaces

If there were to be an intervention within the existing building, the new construction would be assembled rather than built anew. It involves dry construction with only a few materials, echoing the original structure. Various forms of wood could be utilised: solid, agglomerated, cross-laminated, etc. These materials are joined together similarly to textiles, allowing for assembly and disassembly, making the construction "reversible" in nature.

The intervention in the building activates all original elements, incorporating them into the new programme while utilising the physical, spatial, and historical qualities of the structure. This approach enhances efficiency and strengthens the character of the original building in the new construction.

New structures intervening within the existing building will feature contrasting materials to distinguish them from the original structure. This approach ensures that the original building stands out, narrating its own story, while the intervening elements add a contemporary layer to the building's narrative. Similar materials to those existing in the building are reserved solely for repair purposes.

6. CONCLUSIONS

Kuwait's educational journey intertwines cultural preservation and architectural evolution. Traditional Kuwaiti elements, like courtyards and ventilation systems, harmonize heritage with functionality. Adaptive reuse breathes new life into historic school buildings, honouring their significance while meeting modern needs. Interventions introduce contrasting materials to distinguish them from the original structure, adding a contemporary layer while preserving the building's narrative. Results from the proposed framework show enhanced structural integrity, heightened community

engagement, and renewed cultural vitality across the four schools studied. This balanced approach ensures the past informs the present, shaping Kuwait's bright future. ■

BIOGRAPHIES

Rabab Raes Kazem, an architectural designer based in Kuwait, is passionate about using architecture to foster social awareness while remaining mindful of context and time. With a Bachelor of Sciences in Architecture from Roger Williams University and a Master of Arts in Art and Architecture History, Rabab furthered her studies with a Master's in Architecture from California College of Arts. Her focus on architectural heritage and multi-sensory design practices emphasizes architecture as an immersive experience. Currently at the National Council for Culture, Arts, and Literature, Rabab works in the Department of Documentation and Survey of Historical Buildings

Naser Faisal Ashour is an architectural designer and photographer based in Kuwait. He holds a Bachelor of Architecture degree from the New School of Architecture and Design, with a minor in Digital Architecture and Fabrication. Currently, Naser works at the National Council for Culture, Arts, and Literature in the Department of Documentation and Survey of Historical Buildings. Naser also designs and fabricates custom-made gym equipment and furniture. He works on residential and commercial projects in Kuwait and volunteers as a Teaching Assistant at Kuwait University co-teaching Introduction to Historic Conservation for historic buildings, a collaboration between NCCAL and Kuwait University.

IDEAS BEHIND THE FORM: OVERLOOKED QUALITIES OF THE EXPERIMENTAL SCHOOL IN BRATISLAVA

NINA BARTOŠOVÁ
BRNO UNIVERSITY OF TECHNOLOGY, FACULTY OF ARCHITECTURE
SLOVAK UNIVERSITY OF TECHNOLOGY IN BRATISLAVA,
FACULTY OF ARCHITECTURE AND DESIGN

ABSTRACT

The aim of the paper is to show the importance of awareness of the period context related to the design of school buildings in the era of socialism in the then Czechoslovakia, using the example of an experimental school in Bratislava, designed and realized by the prominent Czech architect Vladimír Karfík in the second half of the 1950s (in collaboration with the civil engineer Jozef Harvančík). Especially for the experimental schools, it is not only its fabric, but also its inclusion in the period discourse that justifies their significance and should inform the character of future adaptations. In the case of the school under study, this was not quite the case. Although the current adaptation has not led to any major construction interventions and the building still serves its original function, the (reversible) changes show a substantial disregard for the original innovations. Values of schools built during socialism are often overlooked, along with the fact that architects in the Eastern block – similarly to their counterparts in Western countries – tried to design buildings that adequately responded to the various issues of the time, not necessarily aiming to comply with the communist regime in the first place. In the case of the researched experimental school, the paper builds its argument not as much on the knowledge of Karfík's background – his work experience for Le Corbusier and Frank Lloyd Wright, or for the Bat'a company, which marks his most important realisations – but on archival and field research, and mostly on a content analysis of a book that Karfík co-authored.

1. INTRODUCTION

Czechoslovakia was reunited after World War II, but the interwar democratic regime was replaced by a totalitarian one, subordinate to the Soviet Union. The changed political and economic situation was naturally reflected in the building industry – in the goals it pursued, but also in the technical and material possibilities of construction, while typification and prefabrication became important tools of its economisation. Following the example of the USSR, five-year plans for the development of the national economy were intended to help the effective development of the war-torn country. All this was also reflected in the construction of school buildings, of which there was a shortage after the war, while one of the important priorities of the new socialist state was to enable equal conditions of education and teaching for all as advocated by the School Law from 1948. Therefore, since 1950, typification became the main tool for the mass production of building prefabricated building elements, to increase the volume of construction, reduce labour and speed up construction time. This also meant that the school building layouts and structural types were stabilised for 3 to 5 years which limited the architects' possibility of responding flexibly to new progress[1].

However, some solution was offered by a prototype construction, which allowed, along with the otherwise consistent application of a particular school type, to design a certain percentage of schools according to experimental projects proposed by research and study institutes, universities or state design departments. Although the experimental projects permitted the architects to test different aspects from a pedagogical, architectural or structural point of view, as they were prototypes, the buildings might have been in some respects of a lower quality of execution. This paper seeks to show through the specific example of an experimental school in Bratislava (now Slovakia), that it is precisely why the knowledge of the context and conditions under which experimental schools were built in the former Czechoslovakia, is crucial in order to propose appropriate contemporary adaptations. Ignorance of the former context can lead to an incorrect assessment of the architectural significance and thus to inappropriate building interventions.

Although this paper seeks to highlight the largely forgotten contribution of the school designed by the architect Vladimír Karfík (1901–1996) and civil engineer Jozef Harvančík (1921–1987), it will not attempt to contradict the shortcomings of the building's execution or attribute unlikely qualities to the school's architecture. However, by pointing to the specifics of the time and place, as well as the international context, it will argue that the value of the building lies in the fact that it is one of the few important manifestations of the efforts of Czech and Slovak architects to reflect global post-war trends. The research aims to demonstrate that the design of the school can be read as an attempt to contribute to the formation of a conscious society rather than to "building of socialism" – as it had to be officially claimed – which increases the likelihood that the building will be adapted in the future in alignment with its original innovative features that can still be restored although they have been suppressed over time.

1. Vladimír Karfík, Světla Karfíková and Marián Marcinka. *Nové smery vo výstavbe škôl* (Bratislava: SFVU, 1963), 187.

The arguments presented in the paper are based on the results of architectural-historical research, which drew mostly from archival sources (personal fund of the architect Vladimír Karfík, Brno City Museum), site research, and period journal and book publications. Key outcomes have been obtained by a content analysis of the book *Nové smery vo výstavbe škôl* (New Directions in Construction of Schools??)[2], co-authored by Karfík. In addition, contemporary literature on the topic of school buildings has been studied. The paper is divided into the following sections: description of the school building in Bratislava itself, clarification of the context of the post-war period and the construction of schools on European scale as well as in Czechoslovakia, and lastly Karfík's contribution to the topic of school buildings, awareness of which should be taken into account for future adaptations, as the paper proposes.

2. THE EXPERIMENTAL SCHOOL IN BRATISLAVA

The school in question was built in Mierová kolónia – one of the housing settlements of a large chemical plant in Bratislava[3]. It was a prototype of a secondary (8-year, 9-class) school that emerged from the research task of an experimental project focused on the construction technology of prefabricated schools, which was solved by the research team of the Slovak Technical University in Bratislava in 1956 under the leadership of the architect Vladimír Karfík. Built in 1957, the aim was to test the assembly system, reduce the consumption of building materials, and also to evaluate the classrooms with a square floor plan and bilateral natural lighting in terms of the layout and operation of the building[4]. (**Fig. 1**)

Although the new construction technology ultimately made the building more expensive than the use of a conventional one, it took only 3 weeks to manufacture the building elements and 6 weeks to assemble the building carcass. Despite the fact that the photograph of the school appeared on the cover of the publication *Výstavba škol v Československu* (Construction of Schools in Czechoslovakia) and subsequently in the book *Nová technika a architektura* (New Technology and Architecture)[5], architecturally the project did not impress the professional public very much, as can be understood from the brief commentary by an unnamed editor of the prominent Czechoslovak architectural magazine *Architektura ČSR*, where only one page was devoted to it. Although the editor praised the progressiveness of the layout and the structural system, as well as the fact that the authors preferred square classrooms to the hitherto predominant type of classrooms with a rectangular plan, the architectural expression subordinated to the structural system did not, in his opinion, "sufficiently convey the building's purposeful mission and meaning"[6]. (**Fig. 2**)

However, a more complimentary review by the architect Dušan Kuzma published in the *Projekt* magazine explains that the modular grid of the structural system was determined by the basic layout of the classroom with dimensions of 7.8 m x 7.8 m, which in turn determined the width of the wall panel (195 cm) made of expanded clay concrete, in which the authors also took into account its weight to allow easier transport and installation.

2. Karfík, Karfíková and Marcinka, *Nové smery vo výstavbe škôl*.

3. The factory was founded at the end of the 19th century by the Swedish inventor Alfred Nobel. Several housing settlements for its workers are still in use today.

5. Karel Josef Laboutka, *Výstavba škol v Československu* (Praha: Státní pedagogické nakladatelství, 1957). Karel Storch (ed.), "Nová technika a architektura v Československu", 72-74.

6. *Architektura ČSR* 18, no. 5-6 (1959), 324.

Kuzma describes the interior features in more detail, suggesting that despite the less convincing architectural expression of the building's exterior, the authors took care to create a quality learning environment. The box-like form of the reinforced concrete parts allowed for built-in cabinets and glass display cases to be built into the wall, allowing for a visual connection to the corridor space (**Fig. 3**). Physical well-being of students was to be aided by forced ventilation provided by equipment connected to the heating by means of units located under the windows[7].

The quality of the original spatial layout of the school and classrooms is evidenced by the fact that the building has not ceased to serve the school function – the building was acquired on a 30-year lease in 2004 by the Waldorf School. Although it can be seen as positive that the building remains to serve the school function, and the original spatial concept has proved to be suitable for the current use without necessity of major construction interventions, the adaptation shows a complete ignorance of the quality of the original concept.

3. POLITICAL AND HISTORICAL CONTEXT

Only by understanding the historical and political context – in Europe as well as in Czechoslovakia – is it possible to become more aware of the importance of the school for the local architectural discourse. The period after the end of World War II was characterised by efforts to rebuild war-torn Europe. Among the public facilities that the European governments were interested to invest in, education played an important role. For Western European countries (primarily Denmark, Norway and Sweden, but also the UK and France) education was a means to build a social democratic infrastructure, while for post-fascist states – such as Italy – focus on young children offered an opportunity to "build democracy and long-term resistance to fascism," as Ian Grosvenor and Catherine Burke stress in their book *School*[8]. In Germany, architect Hans Scharoun experimented with ideas for appropriate school design in line with contemporary international concerns for child-centred education and the strengthening of democratic society[9].

At the same time, several countries faced a shortage of school buildings in the early part of the 20th century, and the construction of new schools became an opportunity to support new concepts of education by creating appropriate spaces. Experts and educators alike began to think of the school building as a "third teacher," as schools were expected to fulfil through their design and organisation the notions of a "democratic and egalitarian society," where young people as individuals would be respected, supported in their abilities, and "[n]ursery schools, elementary schools, community schools, and colleges" would become places where societal inequalities could be eliminated[10]. The form of new school buildings was also discussed within the framework of the Commission on School Buildings of the International Union of Architects (UIA) at a meeting organised by the UIA in 1958 in Rabat, Morocco, attended by representatives of several European countries (the Netherlands, Czechoslovakia, Great Britain, Sweden, France, Germany, France, member countries of the Commission)[11].

11. "Compte rendu de la reunion de la Commission des Constructions scolaires a Rabat (4–7 Fevrier 1958)", in *Constructions scolaires, Bulletin information* (March 1958). According to Christine Savonneau (UIA General Secretariat), email message to author, April 4, 2024.

The meeting prompted the drafting of the *Charte des Constructions Scolaires* (School building charter), which, after rectification, was published in 1959[12]. The aim of the Charter was to set out basic principles for school buildings that can be adapted to the specific conditions of individual countries, as the "diversity of problems, the variety of human, economic and geographical conditions, and the rapid development of teaching and construction techniques" did not allow "to develop standards for the dimensions or types of buildings". Although Europe was divided by the Cold War, the UIA meeting in Rabat, Morocco, was attended by architect Bedřich Schránil on behalf of Czechoslovakia, in addition to representatives of Western countries, and the Charter was published in full in the journal *Architektura ČSR* in 1959[13]. It may seem paradoxical that Czechoslovakia, as an Eastern Bloc country, was keen to follow the Charter, since Western countries saw in the schools the potential to strengthen democracy according to the Western model, which was undoubtedly not the goal in the countries under the Soviet Union. But the situation was a little more complex as following section shows.

4. KARFÍK'S CONTRIBUTION TO SCHOOL BUILDINGS

The interest in Western trends most likely reflected attitudes of those architects, who were still influenced by the ideas of interwar democratic Czechoslovakia. From today's point of view, it is not always possible to clearly distinguish between what the architects themselves tended to achieve, and what the regime forced them to do. As architecture historian Veronika Hittmanová Rollová points out, "Left-wing oriented architects had […] considered their profession in a wider social perspective even in interwar Czechoslovakia."[14] But even neutrally oriented architects – among whom Karfík can be counted – were interested in contributing to progress with their work.

Whereas the article by education expert Karel J. Laboutka from 1961 evaluating the post-war school buildings in Czechoslovakia states that according to the 1948 law "conditions were created for the application of the principles of socialist pedagogy"[15], the published texts of the architects show that they were keenly interested in the debate in the West and were inspired by many examples from there. So, while the law promoted a teacher- rather than a student-centred approach in the educational process – which also meant preference of the rectangular shape of the classrooms among other things – architects were not reluctant to test more "democratic" square floor plan classrooms.

Regarding Karfík, and the co-authors of the book *Nové smery vo výstavbe škôl* (**Fig. 4**), architects Světla Karfíkova and Marián Marcinka, it is obvious that in order for the book to pass the censorship, it was not possible to completely omit the obligatory passages characterised by their socialist rhetoric and references to Soviet models. But a closer analysis of the text of the book shows that the authors not only refer to the objectives of the UIA Charter[16], but also to principles that are more in line with trends

in the West. One of them is the square floor plan used in the experimental school in Mierová kolónia. Also, the book's bibliography mentions a number of Western, even U.S. publications.

An interesting finding comes from the analysis of the image material: 65% of the total number of images officially refer to Western school projects in Europe (mostly from Switzerland, Denmark, Sweden, France and also Great Britain), but also the U.S.A. The percentage would likely be higher because the captions for several of the images, which are reminiscent of schools in the West, lack an indication of location. In his review of the publication, architect Vladimír Dedeček highlights the attention paid by the authors to the "basic unit of the school, the classroom, its shape, size and furnishings", where the "variability of the furnishing of the space is emphasised as an important psychological component of the pedagogical process"[17].

The fact that the architects' focus is on the quality of the classroom space and not on the exterior expression of the building is very much representative of Karfík's overall post-war work, where he concentrates on the functional and technical issues of architecture. This is probably why the building, which inspired several school projects in Brno[18], largely fell into oblivion in the past decades. The totalitarian regime that forced Karfík, like other architects, to give up designing in his own office, was not tolerant of either his American experience or his history of working for the capitalist Bat'a. While his postwar professional focus made him acceptable to the communist regime, in 1956 he was even awarded a state prize for his work in the field of progressive building construction; at the same time, as an educator he remained a valued liaison between students and the ideas from the Western world.

5. CONCLUSION

Although the interventions in the experimental school in Mierová kolónia may not be perceived as particularly problematic – they are reversible and the original construction had its shortcomings; this situation highlights a problem that not only the wider public, but also the architects themselves lack sufficient insight and awareness of the work of their predecessors from the relatively recent past. This was confirmed a few years ago when a member of the international jury of an important Slovak architecture prize CE·ZA·AR 2019, attempted to highlight the qualities of an awarded project – adaptation of a school from 1970s – by criticising the original work as "soulless" and "gloomy", typical for architecture built in the period of socialism[19]. One of the older generation of architects, Imrich Ehrenberger (1939), reacted to the situation with justified indignation by publishing a personal reflection[20], which drew attention to the problem of simplistic interpretation of history and evaluation of works.

Similar situations show that school buildings from the socialist period are often quickly and unjustifiably undervalued. Experimental projects are even more vulnerable in this respect, as they are prototypes that may not have been repeated. Their appearance alone, without closer examination and

knowledge of the context, may not speak clearly enough about their overall architectural values. At the same time, a lower quality of construction does not mean that a building does not deserve a responsible approach when adapted. It is the knowledge of the context of the experimental school in Bratislava, whose current state has completely obscured the unique creative efforts of its authors, that points to the importance of paying attention in research to the context that led to its emergence. ■

BIOGRAPHY

Nina Bartošová is an associate professor at the Faculty of Architecture, Brno University of Technology, Czech Republic, and at the Faculty of Architecture and Design, Slovak University of Technology in Bratislava, Slovakia. She is a co-author of the publication *Industrial heritage in the Eyes of Expertise/Experience* (2016), author of number of journal articles on the topic of 20th century architecture and its preservation from a more recent theoretical viewpoint. Her research approach builds on the experience acquired from both architectural practice and academic environment in several European cities. Her long-term research focuses on the work of Bat'a's architect Vladimír Karfík.

SOCIAL SUSTAINABILITY THROUGH ADAPTIVE REUSE CASE STUDY: MT. PLEASANT HIGH SCHOOL – USA

#05

ARMITA EGHBALI
RHODE ISLAND SCHOOL OF DESIGN

MAYA WEBER
RHODE ISLAND SCHOOL OF DESIGN

ABSTRACT

Preserving or reconstructing a building that has outgrown its function has always been a subject for rigorous debate. Adaptive reuse can contribute to a sustainable and culturally rich built environment by preserving and repurposing existing buildings.

The Providence Preservation Society initiated a reuse project using the social sustainability adaptive reuse approach in collaboration with the Rhode Island School of Design to explore the possibilities of reusing all or parts of the historic building of Mt. Pleasant High School in North Providence instead of demolishing and reconstructing it.

During this project, we explored historical documents and interviewed people with different relationships with the school, such as current and previous students, teachers, and neighbors.

Enhancing the neighbors' and students' awareness of the environmental and social aspects of demolishing this building is the primary goal of this investigation. The assessment of cultural heritage is often clouded by public perception, particularly concerning preserving architectural heritage from the Modern Movement era that emerged in the 20th century. While experts recognize Modern Movement artifacts as cultural heritage, the views of non-experts often diverge. By introducing the potential of the building to the community, we hoped to show how a slight intervention can lead to sustainable results and provide a productive learning atmosphere.

The outcome of this investigation is to supply the basis to start an informed conversation alongside presenting a potential solution. The adaptive reuse of the historic Providence High School reflects a community-driven vision for a sustainable future. From its architectural history to generating a new proposal, each step embodies a commitment to conserving and revitalizing the building. This initiative showcases the potential of adaptive reuse to foster social sustainability while simultaneously considering environmental and economic aspects for constructing a future that respects the past while meeting present and prospective needs.

1. INTRODUCTION

A monumental yet crumbling brick building, surrounded by two-story residential housing is the first impression you get when approaching Mt. Pleasant High School.

Early modern buildings now demand some physical and functional alteration. However, functional unresponsiveness is mainly the result of social trends and changes in urban contexts. The causes must be analyzed in order to present a responsive reuse plan.

Searching for the roots of the dysfunction of Mt. Pleasant High School, we found widespread issues affecting the area: namely, neighborhood families are not sending their children to this school. The Mt. Pleasant High School students are shuttled to school from lower socio-economic neighborhoods in the city. These socio-economic differences between the neighborhood and the students are challenging and must be addressed. The overall academic feedback of the students and the school's performance could be more satisfying.

Merely physical improvement could not restore the school's lost reputation. To convince the Providence Public School Society, it needs to remain an academic building with the possible additions.

Mt. Pleasant High School is a public school in Providence, Rhode Island, USA. It was built in 1938 by architects at the Office of the Commissioner of Public Buildings. It is a four-story red-brick-and-limestone building with approximately 300,000 square feet. Two large asymmetrical towers flank the main entrance in the center.

The building's style is on the edge of modernism trends with a steel frame structure, and the main facade follows collegiate gothic. At the rear, the floor-plan follows the function precisely, and the height of each mass section is leveled based on its needs.

The interior is in various states of disrepair. There are holes in the floors and water damage in some rooms. The exterior facade is partly covered in netting to prevent injury from falling bricks. Providence Preservation Society placed it on its Ten Most Endangered list.[1]

According to Providence Public Schools' policy, public schools need less square footage, and the strategy is either demolition and rebuilding or to rehabilitate selectively. The school is a local landmark. It is the tallest building in the area, and the towers can be seen from different parts of the neighborhood.

To prevent the building from being torn down and present an adaptive reuse solution that respects and protects the existing structure, we needed to collect social data and ideas, preferably to come up with a solution that addresses the concerns of the target users: students, neighbors, and parents, with a comprehensive rehabilitation or reuse project, and spread awareness of the carbon consequences if the building is demolished.

2. LITERATURE REVIEW

The main goal of this project was to gather the community's concerns and points of view while involving them in the decision-making related to the

iconic high school in order to achieve a long-lasting and sustainable strategy for intervening or potentially reusing this local heritage.

2.1. ADAPTIVE REUSE

Based on the definition of the ICOMOS New Zealand Charter (2010), adaptation is the process(es) of modifying a place for compatible use while retaining its cultural heritage value.[2] Adaptation processes include alteration and addition.

Adaptive reuse is based on the words 'adaptation' and 'reuse.' The term refers explicitly to changes that involve a functional and physical component that is not necessarily radical.[3] Social trends are noticeable in the majority of reuse cases.

In the past, the practice of altering existing buildings for new uses occurred spontaneously. However, currently, the approaches can be people-led, building-led, or policy-led.[4] the Mt. Pleasant High School project is a combination of the three.

We often appreciate adaptive reuse not only for its environmental benefits but also for the layers of history and meaning embedded in older structures. It contributes to a sustainable and culturally rich built environment by preserving and repurposing existing buildings.

2.2. SUSTAINABILITY

It is accepted that this triad model, in which ecological, economic and social factors are necessary to formulate sustainable development methods. This three-pillar sustainability model has dramatically evolved in developing each aspect independently.[5]

The active NGOs claim that people want the same things: access to clean air and water, economic opportunities, a safe and healthy place to raise their children, shelter, lifelong learning, a sense of community, and the ability to be involved in the decisions that affect their lives.[6] Addressing the particularly relevant local needs while conserving and enhancing the values of our built heritage can be a more intelligent move towards sustainable development, encompassing social and cultural sustainability.

Accordingly, the main goal of this investigation is to consider all three essential pillars appropriately by eliciting the community's concerns and needs.

2.3. COMMUNITY DRIVEN

Engaging the community in design is a process, methodology, or practice of designing with people who will benefit from the design. The ethos of this design model values people by recognizing end users or beneficiaries as the project's primary goal. Whereas architects and professionals can bring technical expertise and particular skills to a given design project, community members bring local expertise and knowledge that designers might lack.[7]

Expanding the concept, community-driven development gives control of decisions and resources to community groups themselves rather than

the planners. These groups often partner with demand-responsive support organizations and service providers, including elected local governments, the private sector, NGOs, and central government agencies. Community-driven development is a way to provide social and infrastructure services, organize economic activity and resource management, empower poor people, improve governance, and enhance the security of the poorest.[8]

According to these definitions, the connected people are involved in the decision-making phase and outcomes of this intervention and reuse design.

3. METHODOLOGY

The building's documentation and data were collected alongside interviews in order to create the building information model for this project.

We started our project at the Providence Archives by looking over historic blueprints and building documents in order to construct a building information model. The BIM model also helped us to calculate the embodied carbon of the building as well as operating energy demands. Our second methodological approach was to conduct interviews. During this project, we tried to speak to as many people as possible, including current students, teachers, students from the neighborhood who went to different schools for the above-mentioned reasons, and the neighbors in the area. We first spoke to an artist living in the neighborhood who built a miniature replica of the school out of Legos. He did this in order to make the building more relatable to others, because it allows a bird's eye view of the structure and engages people of all ages. He proudly described his strong bond to the school - his grandmother was one of the first students to be educated in the building, and his great-grandfather was a bricklayer who built the auditorium. We spoke to other people whose ancestors were also the bricklayers who built this building and learned about their personal connection to it.

By speaking to us, if only for 3-10 minutes each, students had the opportunity to voice their opinions. While a lot of the students were not interested, some took the time to give us their honest answers and started questioning what their learning environment should and could look like. During our interviews, we became aware of the disconnect between the neighborhood and the students. The neighbors were primarily interested in protecting the shell of the building because of its connection to their history rather than its present or future role. The privileged students who went to better-performing schools, were more concerned and focused on the carbon footprint of possible demolition. The students attending the school were primarily concerned with the present condition of the building.

The main consensus we got from interviewing Mt. Pleasant students was that they have no pride in their school, and, therefore, do not care what happens to the building. We quickly realized that finding intersection points between the school and the neighborhood had to be part of a solution.

8. Philippe Dongier et al., "Community driven development." *World Bank Poverty Reduction Strategy Paper* 1 (2003): 303-327.

4. RESULTS

Our conversations and observations helped us create the outline of a social event, including a community charette and ten-day exhibition, to engage the building's current and potential users. Our potential audiences included the Providence Preservation Society, students, neighbors, architects, the Providence School Board, and interested people.

Six posters were provided (**Fig 1**) for this social event to describe and visualize the heritage values of the site and its engagement with urban contexts and residents' memory. Furthermore, the posters clearly explained the environmental implications of demolishing the building in the form of easily understandable infographics. The interactive sections of the presentation illicited their opinions on reconstructing or reusing the building considering the information we made available. The participants were offered a playful surface to stick notes, draw dreams, and compare opportunities.

Additionally, the team has provided their own planning and design as a sample reuse idea (**Fig 2**). This idea was driven by one interview with a girl who felt like nothing she was learning was preparing her for life after graduation. She mentioned that some vocational skills, like cosmetology, could enhance career opportunities.

Accordingly, we propose to replace less than 10% of the square footage of the building, which has not been renovated, with an extension providing a light filled space for students and additional office space. The office space could house: Cosmetology, Architecture/Landscape Architecture, IT, Catering, Dentistry, and Carpentry. These spaces are offered for rent at affordable rates. In exchange, this would offer students a glimpse into these professions one day a week, providing students with real-life experience and exposing them new skills. Businesses could hold weekly mentoring sessions and workshops for students interested in that field, for fee. This will not only inspire students toward future career opportunities but can also bring clients from the neighborhood into the building from a separate entrance. Connecting the neighbors to the school and its novel approach to training would make great strides toward restoring its reputation. This approach would also generate income for the building through rents, which could then be used for educational purposes and improving the well-being of the students.

In terms of physical intervention, we wanted to avoid gutting the entire structure and leaving only the building's prominent facade. In the case of this project, the changes needs to be visible from the street. This is why our suggested addition to the building was the bold gesture of cutting out a small section of the front-facing facade. We want to emphasize that modernization and changes to the existing building have been made, creating a new and inviting space to learn.

We needed to address both student and neighborhood groups - promising the students to update the outdated interior while also catering to the desire of the neighbors to restore the exterior of the building. The new

glass addition allows a look into the building connecting the neighborhood to the life of the building inside.

By opening a section of the right wing of the building and creating an open space, we are resolving the problem of too much unused square footage and aligning it with requirements set by the school board.

By adding a multi-floor light-filled atrium with seating, plants, and bridges, we hope to offer students an intersection between the office space and communal space — a space that invites them to do homework or spend time with classmates outside of class hours.

Environmentally, the building information model provided us with the opportunity to estimate the building's embodied carbon and energy usage and cost. Designers can defend their reuse plans by providing calculations and presenting how environmentally friendly they can be. Also, the effects of retrofit detailing on energy consumption can be measured and analyzed.

Economically, the proposed planning could increase the school's income by renting out the workshops, which can be used for academic purposes and school amenities. This source of income contributes to sustaining the school and enhancing its performance. Unfortunately, the charette did not take place despite the team's preparation and effort. There were several reasons that this community engagement event did not take place, reasons that were not related to preservation.

Initially, the Providence Preservation Society reached out to the Interior Architecture Department of the Rhode Island School of Design about whether students could volunteer their time to research, engage the community, and plan a preservation project. The authors, two graduate students in the post-professional program on adaptive reuse, volunteered. Our research allowed us to create a process for a community charette that presented the positive aspects of reusing structures, especially in an age of climate crisis.

Mt. Pleasant High School, Providence Public Schools, and the RI Department of Education had been proceeding with a plan to demolish Mount Pleasant. After receiving concerns from the community, Providence Public Schools Dept. reached out to the Providence Preservation Society about halting demolition plans and issued a request to study alternatives including demolition, new construction or adaptive reuse.

Despite preparation, this event did not take place. While it was puzzling and frustrating, we came to understand it as a lesson on practice in the professional world where so many factors come into play other than architectural issues themselves. A critical factor was attendance. Despite our planned efforts to promote the event to students by offering them incentive vouchers to local businesses.

The Providence Preservation Society worried they would not be able to attract enough of a broad demographic of community and student attendees for the planned charette event. If that were to happen, a larger ratio of the professional community in attendance would give the appearance of unequal representation, albeit unintended.

In addition, the Providence Preservation Society sensed that there was a high likelihood that the building would be saved, the community would feel less urgency to attend an event to save it, and thus, put the charette event on indefinite hold. PPS is now refocusing its energies towards saving other educational heritage in the city, heritage sites which are smaller in size, and whose preservation and restoration are less complicated and aligned with preservation society's policies.

5. CONCLUSION

As architects, we had a basic preconceived idea of the type of intervention we envisioned before we spoke to the students. We were surprised by their disinterest in the building or their education, so we adapted our approach and took the time to listen. The school officials were envisioning a robotics lab and research center as advancements to rebrand the school; however, these were far from the students' academic interest. We knew we could only understand what the community wanted after we engaged in a dialog. This reinforced the importance of adaptive reuse as a tool to not just restore or rebuild, but also repair relationships between the people using the building and its neighbors. As a result of this communication we not only collected information about the community's needs and concerns but also made them aware of the positive environmental, social, and economic potentials of adaptive reuse for this project.

6. DISCUSSION

While decision makers far from the day-to-day of school life are debating the building's future, the structure is crumbling. This impacts the quality of education, and at the same time creates a greater disconnect between the building and the neighborhood. To avoid this, we need to recognize the importance of community outreach into design.

If the historic building registration list was more inclusive, the arbitrary demolition of iconic buildings like Mt. Pleasant High School could be prevented. In cases where preservation purposes do not align with organizational policies, the registration list would safeguard the building and Providence Public Schools Organization's policy of less square footage for each student would not be a factor threatening Mt. Pleasant's future.

Finally, there are many forms of community engagement. It requires that people be informed in advance about what is happening to get them to attend these meetings and events. If there is no open communication, people forget they have a say. Most people we spoke to felt powerless, forgotten, and demoralized. The students had not heard about any plans for the building. Therefore, we state that before there is community engagement, there needs to be open communication. We had hoped to bring the different voices together in a charette, but instead, we listened to them individually and hopefully motivated them to participate before any further decisions affecting their future are made. ■

BIOGRAPHY

Armita Eghbali is an architect and researcher. With a master's in Conservation and Restoration at University of Tehran and a post-professional graduate degree in Adaptive Reuse at Rhode Island School of Design, RISD. Her research interests are built environment management and adaptive reuse.

Maya Weber is a German American with a bachelor's in scenography and interior architecture from Switzerland, a master's in spatial design from Germany, and a postgraduate degree in Adaptive Reuse at RISD in the USA. Her focus lies in the narrative aspect of spaces, resource-conscious buildings, and structures as cultural heritage.

SCHOOL ARCHITECTURE AND ADAPTIVE REUSE: THE CASE OF THE INMACULADA CONCEPCIÓN SCHOOL

#05

VERÓNICA ESPARZA SAAVEDRA
UNIVERSIDAD SAN SEBASTIÁN, CONCEPCIÓN, CHILE

ABSTRACT

This paper explores the adaptive reuse project of the Former Inmaculada Concepción School in Concepción, Chile. This was originally designed by Emilio Duhart H. and Roberto Goycoolea I. in 1964 and maintained its original use and qualities until 2019, without modifications. However, from 2018 to 2022, a rehabilitation project was undertaken to adapt the building to mixed uses. The project aimed to preserve its original qualities and strategic position in the city while complying with current regulations regarding anti-seismic measures and universal accessibility. In summary, the project successfully balanced the demands of the new owner, regulatory and technical requirements, and the needs of the new commercial uses with the architectural qualities and values, resulting in an adaptive reuse project reasonably favourable to its original condition.

The current operators find it appealing to establish their business in a heritage building like this one, as it sets them apart from their competitors, but unfortunately, they have not been consistent with maintaining and enhancing it.

School architecture is versatile when it comes to prolonging its useful life beyond the pedagogical needs that gave rise to it. Through the proposed case, we aim to show the methodology used to establish the building's qualities and how it contributes to the results of the reuse project and the building's operational phase.

1. THE REALITY OF OUR MODERN HERITAGE

Much of our modern heritage is unprotected by the institutions and instruments that ensure its safeguarding. In many cases, it is privately owned and neither its owners nor its users, that is, nor the society that hosts it, recognise the value of its qualities. In this way, the heritage is at risk as it is exposed to obsolescence, change of use, transformation, degradation, or even disappearance due to the high commercial value that its privileged locations hold. This is all a result of the rapid transformations in today's society.

In our country, there are few successful examples of rehabilitation or adaptive reuse of Modern Architecture for new uses, although there is an increasing interest in investigating, registering and documenting its examples. In most cases, this Architecture is disguised, expanded, intervened, demolished, or ignored without much happening other than complaints and lamentations that quickly fall silent. There are numerous reasons for this complex scenario, some of which are economic reasons or existing legal loopholes. However, fundamentally, it is due to a lack of awareness about the value and meaning of this architecture, which leads to a lack of attachment and sense of belonging.

The city of Concepción was rebuilt after the earthquakes of 1939 and 1960 under the premise of modernity, from city planning to the design of countless single-family homes, public, educational, commercial buildings, or large housing complexes. This heritage goes unnoticed in terms of its quality, despite being used on a daily basis by its citizens. The architectural style, although relatively young, is already more than 50 years old. It reflects economic, technical, material, and social advancements, as it saw itself forced to adapt to changing circumstances and contexts. In this scenario, Modern architecture must adapt to the demands imposed by today's fast-paced world, tackle fresh challenges and adjust to new functional requirements or changes of use. It must therefore undergo a process of renewal, and an adaptation that allows it to remain useful without sacrificing those original qualities and characteristics that constitute its greatest assets.

2. INMACULADA CONCEPCIÓN SCHOOL REUSE PROJECT

2.1. GENESIS OF THE INITIATIVE

In 2014, the Congregation of the sisters of Christian Charity exchanged the 5,500 m^2 grounds of the Inmaculada Concepción school with Inmobiliaria Madesal for new infrastructure located in an emerging residential area outside the city's consolidated centre.

When the news became public, the first voices of concern came from the academic community. Docomomo Chile echoed such concern and wrote a letter to draw the attention of citizens to the architectural value of a building without legal protection, the importance of its authors and the serious impact its alteration or loss would have. It also asked the authorities and the new owners to consider the future of the building and guarantee the preservation of the qualities of its architectural and urban configuration. Days later, an alert about the Duhart and Goycoolea building was published on the

Docomomo International website (April 30, 2015). At the same time, from the academic community, a meeting was requested with the new owners to understand in depth the scope of the real estate project and, on the other hand, highlight the qualities of the building, as well as the importance of its protection as an important piece of our local heritage. Madesal accepted the request, and a first meeting was held with academics and researchers from the four Architecture schools of the city.

Four years later Madesal resumed its commitment made in that first instance and set up a series of meetings to share the progress of the proposed real estate project with relevant actors at different levels to gather opinions and suggestions. Madesal, represented by its General Manager Fernando Saenz Poch, expressed its interest in preserving the Duhart and Goycoolea building through a reuse project that respects its architectural qualities while also adapting to new uses and current regulatory requirements. Consequently, the architects in charge of the project worked alongside a technical advisor who defined and guided the preservation of the original Duhart Goycoolea building.

Fernando Sáenz P. declared that he took on the reuse project as a strategy to capitalise on social profitability, or in other words to fulfil his corporate social responsibility. This receptive and open approach of a real estate agency is unprecedented in the local context, as it welcomes the initial concern and reorients its investment considering this new variable and condition. Furthermore, rehabilitating an existing building is understood as advantageous since there is significantly less damage to the environment by avoiding the carbon footprint associated with the entire demolition and construction process.

2.2. CRITICAL ANALYSIS OF THE ORIGINAL PROJECT BY DUHART – GOYCOOLEA

For a reuse project, in-depth knowledge of the building to be intervened is considered a crucial starting point for an architectural design process that adapts it to current demands. It was imperative to identify and highlight the valuable qualities of the Inmaculada Concepción School, designed by Duhart[1] and Goycoolea[2] in 1964, in order to preserve them. (**Fig. 1**)

The critical analysis of the original project established architectural values on three levels: spatial, compositional and constructive-structural qualities. In this way it was defined:

2.2.1. SPATIAL QUALITIES

1.- Spatiality of the main school entrance: degree of transparency, proportions, degree of lighting, interior-exterior relationship, façade setback and elevation from street level.

2.- Elevated horizontal plane: interior definition of the hall and ceiling of the first-floor circulation, scaling and tensioning said space. Furthermore, as it extends towards the street, it transforms into the distinctive wide canopy that greets and accompanies the pedestrian's passage.

3.- Scale box volume and bathrooms: This volume takes into account two relevant spatial qualities. On the one hand, at all levels it has a spacious

1. Emilio Duhart Harosteguy (1917-2006), who graduated as an architect in 1941 from the Pontifical Catholic University of Chile. In 1958, after 12 years of partnership with Sergio Larraín G.M. He founded his own office in Santiago: Emilio Duhart Arquitectura y Planning, an office that would last until 1969, when Duhart emigrated to France. During this period, his most notable works are found, such as the United Nations building for Santiago de Chile, 1960 – 1966, today ECLAC. In 1960, the office opened a subsidiary in Concepción thanks to the professional partnership with Roberto Goycoolea I. Duhart received the National Architecture Prize in 1995.

2. Roberto Goycoolea Infante (1918 -2018) was a Civil Builder and Architect, he graduated as such in 1958 from the Pontifical Catholic University of Chile. He was a former student and collaborator of Duhart in his office in Santiago and from 1960 his partner in Concepción, the city where he moved to live. He received the National Architecture Prize in 1995.

circulation space around it, which isolates and highlights it. On the other hand, inside, it consists of two subspaces, of which the most prominent is the scale box that is bathed by overhead light.

4.- Spatiality of the 2nd and 3rd floor circulations: height and width of its development, its clear linearity and mainly the interpretation of the structural solution of the project that shapes and tensions its route.

5.- The inner courtyard is a significant open space for the project, due to its configuration and height, it ensures the quality of the interior natural lighting.

2.2.2. COMPOSITIONAL QUALITIES

1.- Main facade. Markedly horizontal composition with a clear differentiated reading of the 1st -, 2nd - 3rd level and 4th terrace level:

1st level: This is primarily focused on reading and pedestrian recognition. This composition is defined by three degrees of permeability that contrast opacity, transparency and a very characteristic sieve or framework. In the centre of the composition, the protruding canopy prioritises the main access.

2nd-3rd level: The composition of the façade is rhythmised by the heads of the structure's beams. The presence of the beam is exalted by a continuous horizontal window that is slightly set back from the plane of the façade. At these levels there is balance in the composition of full and empty spaces.

4th Terrace Level: The original project featured a light isolated volume with a "butterfly" roof that constituted the upper part of the building and was visible from the street level.

2.- Solid volume of scale and bathrooms. This volume has a clear reading in the composition of the façade and balances its horizontality. In plastic terms, the use of colour in the coating used adds value to the element.

3.- Encounter with an adjacent building. The composition of the volume is recognised as a unique quality of the original project, as it is set back to align with the adjacent building, creating a solid "floating" volume. At the terrace level he proposed a very innovative elevated garden for its time that was even planned vertically to climb and cover the upper section of the South façade of the neighbouring building. However, this aspect of the original design was never carried out.

2.2.3. CONSTRUCTIVE - STRUCTURAL QUALITIES

1.- Structural system. The beams and pillars that make up a modular arrangement in a transverse direction, alongside the slab, create a system that has no more bracing in a longitudinal direction than the solid volume that contains a scale box and bathrooms. This structural solution is always visible in the interior or exterior space.

2.- Steel construction solution to "hang" the canopy. There is special care in the design of the construction detail of this element and it can already be seen from the main entrance hall to the building.

3.- Free Plant. The building's structural system defines free floors with reinforced concrete pillars with a circular section on the 1st level and a rectangular section on the upper levels.

2.3. ADAPTIVE REUSE

"*The best way to preserve a building is to find a use for it*"
Viollet-le-Duc, 1854

#05

It is crucial to reuse heritage as a sustainable response to preserving fragile heritage in local contexts. An intentional reuse project where the pre-existing and the new coexist in harmony means prolonging the useful life of the building. In this sense, Soria and Guerrero[3] state that the challenge for the architectural project that wants to effectively adapt a building of heritage value is to be a tool that manages, on the one hand, to maintain the values that allow for preserving the memory of what is intervened and on the other hand, create contemporary spaces that respond to current needs by providing added value, in other words, highlighting the past, interpreting the changes and needs of the present and safeguarding the future.

The bibliographic review suggests that consciously projecting on pre-existing buildings can be a means of heritage preservation. Contemporary architectural design, therefore, has room to contribute since "the wide range of use possibilities for a wide range of places of different qualities becomes evident, which become necessary within the dynamics of today's society, recognising the value of pre-existence and non-substitution", this necessarily implies a degree of modification for effective adaptation. In the case of the school, it means rehabilitation to house mixed uses that include retail, cafes, and offices. Operators find it appealing to establish their businesses in a historically significant building like this one because it sets them apart from their competitors, as long as it considers the characteristics and qualities of the space it is using and is consistent with it.

On an urban level, the successful completion of the reuse project is expected to stimulate the commercial regeneration of its immediate surroundings. The Rehabilitation of the Duhart and Goycoolea building will become the access threshold to a larger real estate development within the block that includes commerce, offices, and apartments and that also aims to connect to the existing network of galleries in the city, another characteristic space rooted in its collective memory. (**Fig. 2**)

3. FINAL CONSIDERATIONS

The case examined here is undoubtedly unique, not only because of the authors of the work, their qualities or the challenge it implied for the professional team, but also because of the attitude assumed by its owner, since he calculates the enhancement of the building beyond the immediate economic benefits. The outcome of the rehabilitation project is considered quite positive, as it represents a turning point in the approach towards real estate projects that integrate Modern Heritage in the city. In this sense, it can contribute to better practices from contemporary architecture, and real estate management in favour of the preservation of our built heritage.

Contemporary interventions are necessary to sustain modern heritage, both materially, physically and culturally. When it comes to school architecture, it

3. Francisco Soria and Luis Guerrero, "El proyecto de reutilización arquitectónica: hacia una valoración ampliada del patrimonio edificado", *Academia XXII UNAM*, no 13, (2016): 127- 143.

can involve maintaining its modern characteristics while also incorporating new interventions that distinguish it with respect to pre-existing architecture. Contemporary interventions on modern school heritage, as represented in this case, determined a complex network of relationships and actions that did not always work in unison. The demands and priorities of the owners, regulatory requirements and needs of its users (which may not always be consistent), input from professionals responsible for the projects, the assessment of citizens and specialists, economic constraints, and numerous other factors represent the current reality of Modern Heritage in our country.

When the rehabilitation project began, the school suffered from a general lack of recognition and awareness of its original values, qualities or characteristics among the congregation and the general public. Only academics and specialised researchers recognised its qualities as such, that is, a very small circle of actors. Only when the threat of demolition, in other words, the loss of the building was assumed, were voices raised, and the school's alumni and civil society turned their attention to the project.

In this sense, the role of specialised criticism is, therefore, to EDUCATE, socialise, and broaden knowledge about buildings, architects and their contexts. The purpose is to record, classify, and safeguard, not prevent, from the perspective of this research, the necessary adaptations and processes of change, but rather to support the respectful consideration of the fundamental values of modern architecture.

The architecture office responsible for executing the rehabilitation project served as a mediator, and facilitator between the various parties and factors involved in this adaptive reuse process. However, no one anticipated that the project's implementation phase would not align with the significant effort put into it. What was originally understood as a good practice (despite the complex and cumbersome challenges of the pandemic) to adapt work in a sustainable way to current needs, has been hindered by the tenants, those who occupy the building and do not recognise its qualities or its internal logic. They only prioritise their individual interests, focusing solely on functionality and economic profitability, while overlooking the effort, relevance and impact that a work of these characteristics has. Unfortunately, the poor condition of the rehabilitated spaces has been detrimental to the original qualities of the work and how they are perceived by users.

The rehabilitation of this building, from the perspective of this research, has guaranteed the historical relevance of the building, not only by preserving its useful life but by keeping its memory alive for hundreds of young women who were educated in its classrooms. The building holds a place in the collective memory of the city, representing the education and values of Catholic upbringing for a segment of the population, although it is unaware of its architectural values. Its former students today revisit the building to go to the offices, medical appointments, pharmacy or cafeteria, and they recognise the old spaces in the facilities to varying degrees of certainty.

The building's external appearance remains unchanged, preserving the original facade's composition, proportions, rhythm, and distinctive elements.

However, the materiality was updated. Changes were made mainly in the spatiality of the old classrooms to adapt proportions, circulations, etc. to new uses thanks to the open floor plans and the structural system that the original building provided.

Modern school architecture and in this particular case, its qualities, including its strategic urban location, spatial distribution, construction techniques, structural system, aesthetic quality and use, as well as its intangible values such as historical significance, and social impact is, without a doubt, a reference to establish the relevance of this typology as architectural heritage and a way of ensuring its transition to the 21st century through adaptive reuse projects that allow us to value and preserve our heritage sustainably. ■

ABSTRACT

Modern school buildings face a demanding challenge when renovation implies adaptation to contemporary teaching and learning experiences in schools. At the Department of Architecture of the University of Coimbra (DARQ-UC), two Erasmus-funded projects – Reuse of Modernist Buildings (RMB) and Collaborative Redesign of Schools (CoReD) – were developed to create methods and tools to answer these challenges by engaging the school community in the design process.

Meanwhile, the Municipality of Coimbra called for tenders to carry out a research and action project for the former Coimbra lyceum – José Falcão Secondary School – designed in 1930 and built in 1936. DARQ-UC was selected to test the participatory methodologies developed within a research environment into a real case study. Although pedagogical activities are still functioning, the building faces several challenges due to construction pathologies and the new functions that were added during the last 90 years of continuous activity.

The paper focuses on the participatory process carried out with the school community to create the functional programme together and rethink the use of the existing school spaces according to the experience of those who use the school every day to learn, teach and work. The research activities were based on the S3S methodology (CoReD) and involved surveys, walkthroughs, workshops, interviews, and a school assembly, involving 500 participants. The dialogue with the community highlighted the qualities of the building and also the needs related to functionality, accessibility, sustainability, and intersectionality. The final programme proposed by the research and design team is the product of the dialogue with the community

voices and modern building principles (RMB). Nevertheless, the participatory process is a territory of negotiation with consensus and conflicts, where "the existing building will dictate the rule for what is possible (...) it will establish the limits of transformative intervention"[1]

1. INTRODUCTION

Projects for schools were the first to explore modern principles by building on the 19th-century rationalistic experience, namely by including rows of classrooms, laboratories, gymnasiums, and swimming pools, among others.

Today, many of these schools are still functioning but they need to be renovated in architectural and educational terms due to the degradation of the environmental conditions and the inadequate educational facilities. The reuse of these modern school buildings suffers from their functional character, which hinders their contemporary educational needs and from their constructive fragility due to the innovative and experimental solutions employed.

These buildings were built in modern urban areas, related with housing neighbourhoods, and played an important social role as community centres. Today, they are more than educational facilities and have become part of the everyday life of the cities, used by generations that developed a sense of belonging with the space, architecture, furniture, and objects.

Collaborative redesign with a participatory approach becomes more and more relevant when the buildings have a social dimension and several actors can contribute with their everyday knowledge and experience.

2. JOSÉ FALCÃO SCHOOL (1930–2023) – HISTORY AND TRANSFORMATION

In Portugal, the design of school buildings follows the international state of the art with several projects for high schools developed in the first quarter of the 20th century according to this rationalistic approach. Nevertheless, the new political regime and the opening of the architectural culture to modernism during the 1920s created the conditions for a new perspective on school buildings. The state organism responsible for schools' maintenance and construction opened a set of competitions for new high school buildings[2].

The José Falcão Lyceum in the city of Coimbra is the result of one of these competitions where young architects presented modern proposals inspired by European references but also learned from the rationalist experience. The team of Carlos Ramos, Adelino Nunes and Jorge Segurado won this competition in 1930 with the project Santa Cruz, a tribute to the first convent that functioned as a school **(Fig. 1)**. The project is an interesting combination of modern structures: it has the rotunda that organises the entrance block with the atrium, staircase, library and amphitheatre, or the sports pavilion with several circular elements and galleries connecting the main building; it also has more classical elements, namely the internal patio and the rows of classrooms.

The school has been functioning as such for 88 years and has become part of the city landscape and everyday life. The school community that worked and studied here over the years developed a strong sense of

1. Alexandre Alves Costa, *O Liceu Alexandre Herculano, no Porto. História, Projecto e Transformação* (Porto: FIMS, 2011), 49.

2. Gonçalo Canto Moniz, *Arquitetura e Instrução: O Projecto Moderno do Liceu, 1836-1936*, (Coimbra: eldlarq, 2007).

belonging. This is probably the reason for the very good condition of the buildings although in some cases, some transformation has changed the modern character to solve specific needs.

Five main transformations that had an impact on the modern design can be identified. The first took place immediately after the opening of the school, in 1936, to increase the number of students with a new floor in the west and south blocks of the main building. This transformation was designed by one of the three authors, Carlos Ramos, but the two other authors considered it unacceptable and withdrew their authorship. The second was the replacement of the swimming pool with an auditorium and a small gymnasium in1960s. The third was the construction of the changing rooms and three classrooms for the sports pavilion in place of the covered open-air playground. The fourth was the replacement of the wooden windows with aluminium in the 1970s. The fifth and latest transformation was the expansion of the canteen and gymnasium.

3. PARTICIPATORY DESIGN

3.1. STATE OF THE ART

Since the late 1960s, collaborative design has been challenging architects to rethink architectural design practices in a participatory approach that engages the local community in the design process. In 1971, Giancarlo de Carlo called for an architecture of participation where "architecture will abandon the authoritarian position and will become part of the people, and people will defend architecture"[3]. In fact, De Carlo was criticising the modern architects that produced beautiful buildings without taking in consideration people's needs but applied rational programmes based on technical logics. There is thus an opportunity today to revise history and redesign the building according to the users' experience and real needs. The collaborative redesign of modern school buildings highlights this challenge by bringing modern and contemporary architecture and education into the dialogue.

3.2. METHODOLOGY

3.2.1 CORED AND JOSÉ FALCÃO SCHOOL

At the Department of Architecture of the University of Coimbra (DARQ-UC), two European Erasmus-funded projects were developed to create methods and tools to answer these challenges by engaging the school community in the design process, namely the RMB project – Reuse of Modernist Buildings and CoRed – Collaborative Redesign with Schools.

This latter, involving the same team of researchers, provided the knowledge base for the participatory process implemented at José Falcão School, by using the CoReD's participatory tool named Survey on Student School Spaces (S3S), which aims to collect student feedback on their schools, uses and feelings. Ultimately, S3S acts as a post-occupancy evaluation tool, to consider possible co-creation and co-rehabilitation actions with the school community to better align learning parties and spaces and their effective uses and appropriation.[4]

S3S is a twofold process that comprises an online survey about users' feelings and activities in five types of spaces: outdoor spaces, formal learning

3. Giancarlo de Carlo, *L'architettura della partecipazione* (Milan, Quodlibet, 2015), 78.

4. Carolina Coelho, António Cordeiro, Luís Alcoforado and Gonçalo Canto Moniz, "Survey on Student School Spaces: An Inclusive Design Tool for a Better School," *Buildings 12*, no. 4 (2022): 392 https://doi.org/10.3390/buildings12040392.

spaces, study spaces, eating spaces, and communal and circulation spaces. Then, it involves focus groups such as walkthroughs, to detail the data previously collected. Finally, the school community is gathered in a school assembly to collectively engage all the community and to negotiate future actions on space.

The participatory process at José Falcão School Is being implemented in two main stages:In the first trimester, participation was undertaken to understand how the building is organised, how the spaces are used, which spaces are the most relevant and which spaces are lacking or need to be rethought. In the final trimester, the community will be involved again in order to assess the impact of the refurbishment on the school's day-to-day life, acting as post-occupancy evaluation.

Additionally, during the intermediate phases, the school community will be invited to take part in specific activities, helping to make decisions about the particular architectural options.

4. REHABILITATION OF JOSÉ FALCÃO SCHOOL

4.1. PARTICIPATORY PROCESS

This paper will focus on the participatory process carried out with the school community in the initial stage of this project, implemented between December 1, 2023 and January 31, 2024.The intention was to create the functional programme together and rethink the use of the existing school spaces according to the experience of those who use the school every day to learn, teach and work.

In the refurbishment project for José Falcão School, the CoReD methodology was reformulated due to the need to involve the different stakeholders: a large number of students, teachers, staff, parents, alumni, and institutional partners. Thus, the research activities were based on the CoRed's S3S methodology, including surveys and walkthroughs and a school assembly, but also comprising workshops and interviews. This process engaged 500 participants overall, who were very enthusiastic about contributing to the process from the start and willing to take part in the activities.

4.1.1. SURVEY

The conducted survey encompassed input from all members of the educational community to grasp their needs and perspectives. Queries delved into frequency of usage, activities conducted, and participant perceptions regarding each space, aiming to elucidate the activities and sentiments associated with each. The 524 responses provided a holistic understanding of the different community viewpoints and educational needs.

The analysis of responses underscores a substantial student representation (80%), compared to teachers (16.9%) and staff (3.1%). The inner courtyard emerged as a valued space, although its restricted access limits its utility. The outdoor recreational area faces challenges in use due to maintenance issues and a lack of equipment. The entrance stands out as a widely utilized space, establishing itself as the "face" of the school for the city and as one of the

school's elements of identity, while the library, positioned above, experiences relatively low usage and, though it is appreciated by visitors, suffers from outdated furnishings and books. Classrooms and corridors encounter similar challenges, including thermal, acoustic and ventilation issues, though their ample dimensions and natural light are commendable features.

4.1.2. WALKTHROUGH

Walkthroughs are group activities involving visits to comment on school spaces conducted in two modalities. Firstly, walkthroughs aimed to clarify survey results by visiting spaces outlined in the questionnaire, organized according to survey categories. Secondly, tours with representatives from associations or specific groups gathered the perspectives regarding the school spaces that were considered of particular interest to them. Fourteen walks were conducted in total, of which ten were aimed at specific groups. University of Coimbra researchers recorded participants' comments using template sheets **(Fig. 3)**.

The comments corroborated and expanded upon the survey feedback, but also touched on various areas of concern. For instance, the laboratories exhibited notable discrepancies in capacity and student numbers, with issues of comfort, acoustics, and adaptability. Lighting and ventilation problems were highlighted. The sports complex showed the necessity of improving accessibility and refurbishing classrooms. Finally, the comments of the Inclusive Education group were crucial, since the spaces dedicated to them face challenges of location, organisation, and accessibility, with insufficient water points.

4.1.3. WORKSHOP

Workshops were conducted in an enclosed setting, targeting groups that do not utilise every school space in their daily routines. Firstly, participants sit around a table with photographs representing school spaces, select one, and use it to comment on the place. Subsequently, they organised themselves into groups around a poster displaying the school's floor plans to discuss areas of interest and common issues, recording them on post-it notes later affixed to the panel. A spokesperson from each group presented the discussions. In addition to three planned workshops, there were spontaneous meetings with four groups, prompted by time constraints or late hours, showcasing the simplicity and ease provided by this tool.

The general comments were aligned with those from other activities but provided additional insights into less-discussed spaces, such as the central stairs, which, although imposing, face challenges related to accessibility, climate control, and safety; the amphitheatre, notable for its location and antique furniture but lacking in thermal comfort, modern equipment, and proper furniture maintenance; the gymnasium, where issues of insufficient changing rooms and the need for a covered outdoor space for students must be addressed; and the cafeteria, a social hub that requires enhanced attractiveness, particularly during winter months.

4.1.4. INTERVIEW WITH THE SCHOOL DIRECTOR

The interview served as a pivotal moment in the community participatory process, consolidating themes from previous procedures. The interview was conducted by two research team members who followed a script that was shared previously. It provided insights into the educational strategy, school's daily operations, enhancing our understanding of the current situation and offering recommendations for the project team. Key points included ensuring accessibility for all and addressing specific management space requirements.

4.1.5. ASSEMBLY

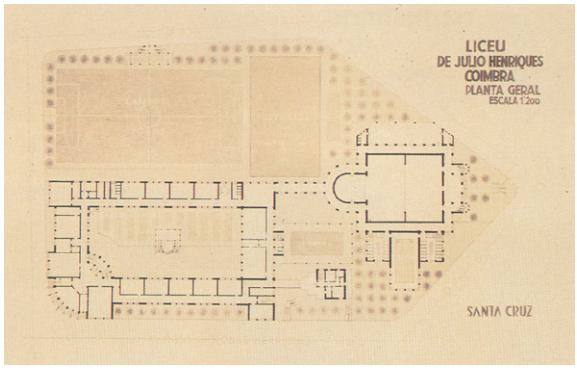
To close the first stage of the participatory process, an assembly was organised -in four moments- to present the co-diagnostic and design strategy and to discuss these results. Firstly, two projects were presented related to interventions in two high schools carried out in the frame of Parque Escolar[5]. Secondly, the team presented the co-diagnostic and design strategy. Thirdly, the school community and guests were invited to split into four rooms to discuss one of four key spaces – entrance, students' room, classroom and sports spaces. Fourthly, the groups return to the amphitheatre to share the results of the discussion from their room.

The results were balanced between supporting the strategy, co-creating new proposals and some resistance to specific changes.

The "entrance" group highlighted the need for an entrance which is accessible for all and the need to control the speed of traffic in the main avenue in front of the school.

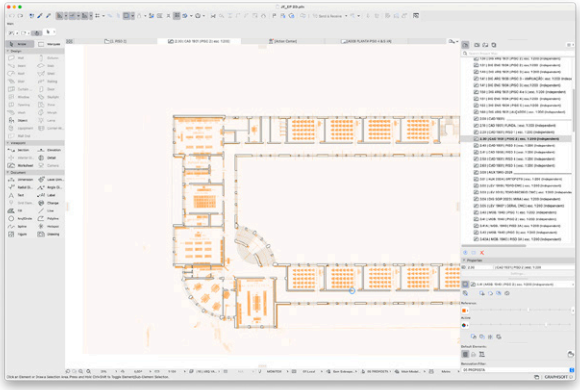
The "students' space" location opened to the patios was approved but they made some recommendations for more convivial spaces outside: sports equipment outside, toilets, non-chromatic materials and parking for bikes and motorbikes.

The "exterior spaces" group proposed the renovation of the alley with a new entrance with more dignity, namely with benches and tables, water spots, information panels and parking for bikes. This group discussed the sports pavilion, particularly the transformation of the auditorium into a flexible space that could have mixed use – canteen and auditorium. This solution was proved polemic and the project was revised to keep the autonomy of the auditorium.



The assembly was not only a space of presentation and discussion but also a space for decision-making.

4.2. DESIGN STRATEGY



The spatial reinterpretation of the school layout departed from an in-depth analysis of the whole life span of the 88-year-old building. Since the initial project from 1931, all the changes introduced during the construction phase until 1936, the expansion of 1938 and all adaptations throughout 1940s, 1960s and early 2000s, were all considered and evaluated with their own strengths and weaknesses.

Given the large number of transformations implemented throughout the last nine decades, sorting out the archive documents was almost a project in

Figure 3. Snapshot of BIM organization of historical sheet layers, georeferenced and overlaid. May 6, 2024. © CEARQ-TD Archive.

Figure 4. First diagram presented in the first school seminar, as a result of the first participation sessions and architectural analysis. January 24, 2024. © CEARQ-TD Archive.

itself. In this sense, the use of BIM software was valuable from the very first moment. By georeferencing all projects in digital sheets layers, the team was able to trace and compare every single variation of the physical layout of the building. This kind of digital palimpsest contributed to a quick and thorough understanding of the evolution of the case study **(Fig. 3).**

All this historical data was then compared with the knowledge fostered by the participatory process. The inputs received from the school community were crucial in the process of outlining the main action lines of the project, such as: opening up and connecting the courtyards, creating a main gathering

room for the community and bringing the layout back to its original and clearer organisation.

These ambitions were analysed through the lens of the new pedagogical project for a progressive and inclusive school that aimed at reshuffling and adapting the lyceum's layout to future needs. The layout of the classrooms was reconfigured for a more inclusive and horizontal way of sharing knowledge. The corridors and atrium were reconsidered as spaces for encounters and for spending time, with the idea in mind of embracing the learning process outside of the traditional classroom environment.

The programmatic organisation of the school, which underwent many changes in the past, is now proposed to be clarified following the initial composition principles laid out by Ramos, Nunes and Segurado. Major classes will be located in the longer corridors, exceptional classes, such as science labs and design labs, will be on the two edges of the building with its specifically sized rooms. The bar and break room is proposed to be relocated to the south wing, on the ground floor, becoming not only the central gathering space but also connecting the two patios that had barely any connection and outside usage **(Fig. 4).**

The design strategy is not going back to the initial design, but establishing a balance between the initial modern composition principles and the new spaces for a contemporary education. In some situations, transformations are needed, but in other demolitions are necessary. This strategy follows Alexandre Alves Costa when he refers to Alexandre Herculano School rehabilitation, "the existing building will dictate the rule for what is possible (...) it will establish the limits of transformative intervention"[6].

5. CONCLUSIONS AND LESSONS LEARNT

As part of the process of participation by the educational community at José Falcão Secondary School, some methodological constraints and lessons learnt stand out. The whole community was very enthusiastic about the process and willing to take part in the activities, due to a strong sense of belonging. Since various activities were planned ahead, including walkthroughs, workshops and meetings, these required some flexibility in their implementation to accommodate the school schedule and actors availability.

We can conclude that participatory proximity is crucial to foster close dialogue with the entire school community during the participatory process, opening up various channels of communication, such as email, telephone or messaging. The school director also acted as a facilitator of the communication between all stakeholders, helping to coordinate the timetable for the various activities and those involved in each one.

Lastly, given the variety of participants involved, in terms of the type of experience they have in school spaces, their ages and personal, social and professional contexts, there were sometimes contrasting points of view about the same space. These situations had to be managed by the project's team of researchers, the points of view mediated, and the underlying arguments understood. Thus, we know that the proposed

6. Costa, *"O liceu"*, 49.

spatial definition is not the consensus of all those involved, but is the result of a mediation and negotiation of contributions from many stakeholders involved in this process. ■

BIOGRAPHY

Gonçalo Canto Moniz is associate professor at the Department of Architecture of the University of Coimbra where he graduated in 1995, and obtained his PhD degree in architecture in 2011. He is a researcher at the Centre for Social Studies of the University of Coimbra, where he co-coordinates the thematic line Urban Cultures, Sociabilities and Participation. He is co-PI of two European projects: URBiNAT (H2020, 2018–2024) and TRANS-Lighthouses (Horizon Europe, 2023–2026). At DARQ-UC he is co-coordinating the renovation of José Falcão School. He is a member of the DoCoMoMo ISC Education and Training.

João Mendes Ribeiro is a graduate of the Faculty of Architecture of Porto University (FAUP) and he has been associate professor at the Department of Architecture of the University of Coimbra (DARQ-UC) since 1991. He presented his doctoral thesis in 2009, in the field of theory and history, on the relation between architecture and scenography. His professional practice has been recognized with awards and publications, such as the renovation of the Botanical Garden of Coimbra winter gardens and the Contemporary Art Center of São Miguel Island in Azores.

Carolina Coelho is invited assistant professor at the Department of Architecture of the University of Coimbra (DARQ-UC) in theory and history of architecture and subjects associated with architectural research, and is an integrated researcher and member of the Scientific Coordination Board at the Centre for Interdisciplinary Studies (CEIS20). She presented her doctoral thesis at the Centre for Social Studies (CES) and DARQ-UC, researching "Life within architecture from design process to space use. Adaptability in school buildings today – A methodological approach". She participated in the project "(EU)ROPA: Rise of Portuguese Architecture" and coordinated the Portuguese research team in "CoReD: Collaborative Re-design with Schools".

Pedro Brígida has been invited assistant professor at the Department of Architecture of the University of Coimbra (DARQ-UC) in architectural design and construction since 2010. He has a professional practice together with Alice Santiago Faria, with awards and publications. Their work ranges from small scale interventions, such as dwelling renovations to larger facilities such has the Colmeal Hotel or the Day Care Centre of Marialva. He has a special interest in furniture design and has shared the equipment design company ZTDA with Eduardo Mota since 2001.

Duarte Miranda is an architect who graduated from the Department of Architecture of the University of Coimbra (DARQ-UC), where he presented his master's thesis on the design process of Álvaro Siza in Van der Venne Park, in the Hague, in 2017. He worked between 2016 and 2022 in Gent, Belgium, and since January 2024 at the Centre of Architectural Studies, from Territory to Design of the University of Coimbra (CEARQ-TD).

Valentina Leal Gutiérrez is a final-year student at the University of Coimbra's Department of Architecture (DARQ-UC). Currently, she is finalizing her master's thesis, which delves into the implications of integrating participatory processes into architectural design. Having contributed to the team implementing participatory methodologies in the rehabilitation project of José Falcão Secondary School, her research aims to highlight the benefits of community involvement in creating inclusive spaces.

HEALTHCARE COMPLEXES: THE FUTURES OF MODERN URBAN ENCLAVES[1]

ABSTRACT

Hospitals and health complexes, viewed from an urban dimension, have played a pivotal role in shaping the networks and structures of cities and urban areas. Over time, as part of the modernisation process, health architectures have become increasingly complex. Beginning with the pavilion-style hospitals of the 18th century, which established the hygienist model as centres of healing and scientific practice, we have progressed to the 20th century, witnessing the emergence of various typologies that prompted discussions about their place in urban spaces.

The urban configurations and appearances of modern hospitals reflect the evolving complexity of their programmes, successive redefinitions, and the gradual incorporation of services, equipment, and technologies. The design of hospital complexes is a result of intellectual reflections and decisions, with their urban locations playing a crucial role in determining their organisation, scale, and volumetric composition.

Modern hospitals have adapted to new construction techniques and scientific advances. Initially characterised by concentrated, vertical blocks organised as complex sanitary systems, these complexes have evolved to accommodate various typological variations.

Throughout the 20th century, we have witnessed the design of hospital complexes aimed at consolidating different healthcare functions, often incorporating new services into existing modern hospital buildings. These health complexes serve as urban enclaves, attracting large numbers of people and playing a prominent role in their surroundings.

The focus is to analyse the relationship between modern health complexes and contemporary cities. This includes examining their historical origins, current uses, and future prospects in light of the evolving challenges faced by cities globally. From the ongoing adaptation and expansion of buildings in cities to considerations of obsolescence and inadequate locations, questions arise as to how to manage these modern legacies. Should they be adapted to meet contemporary needs, repurposed, or replaced with new complexes?

1. INTRODUCTION

Health and hospital architecture in modernity have been part of the research interests of the organisers of this session since the early 21st century, with particular attention paid to these processes in the context of Latin America. They have been actively involved in the Ibero-American Network of Historians of Hospital Architecture, as well as its five International Seminars, starting with the first one organised by Amora and Gama-Rosa Costa in Rio de Janeiro in 2014. Furthermore, at the same time, and with a more urban focus, sessions have been organised at the three Congresses of the Ibero-American Association of Urban History.

The hospital building in modernity, conceived as a healing machine[3], emerged in the 18th century as an urban function alongside other modern programmes such as prisons, schools, and collective housing, all of which directly contributed to the modernisation of urban society.[4] Modern architecture in the 20th century symbolised efficiency and hygiene, and such principles were considered fundamental to the development of the most rational of modern buildings: the hospital.

Moreover, health has been a constant concern in state and professional interventions in urban space. Throughout the 19th century, "hygienist" and "sanitarist" principles guided modernisation projects, introducing new modes of planning public spaces and new models for hospital architecture. The formal typology of hospitals organised into pavilions, initially based on the 19th-century French model of Durand's articulated pavilions, was reconsidered to accommodate different hospital programmes. The shift in the logic of hospital placement within cities, prompted by the late 19th-century transition from the miasmatic to the Pasteurian paradigm, did not occur instantly. The idea of the hospital as an exceptional enclave remains a guiding factor in design decisions to this day.

2. FROM SITE STRATEGIES TO URBAN PROJECT

The hospital or healthcare complex, understood in its urban dimension, was one of the first facilities to contribute to the consolidation of urban service structures. Health architectures have gained significant complexity throughout the processes of modernisation. Starting with the pavilion-type hospitals of the 18th century, which shaped the hygienist model as places of healing and scientific practice, up to the 20th century, with the definition of different typologies and technological developments that required debating the place of these functional typologies in the city space and urban context.

The early pavilion complexes of the 19th and early 20th centuries, despite the fact they were not modern in expression, employed modern strategies. Among these, urban considerations for selecting their locations were derived from the knowledge and problems of the time. For example, to address the issues arising from increasing migration, industrial pollution, and the scarcity of water and sewage networks, procedures were recommended for choosing healthy land.[5] Mumford perceived the counterattack to the pestilential industrial city through the "art of sanitation or public hygiene,"

and the improvement of prisons and hospitals transformed them into "pilot plants" for urban space reform.[6]

Hygienists recommended that hospitals should be located away from urban conglomerations, placed outside cities, close to accessible roads, on healthy land, downstream from the population, and downwind from prevailing winds. Additionally, the terrain should have a slight slope, avoiding valley bottoms and marshes, and should be situated on the middle part of a hillside. These recommendations were associated with certain favourable ventilation conditions. They also suggested creating a protection zone around hospitals consisting of parks and gardens.[7]

In the early decades of the 20th century, some aspects to consider in the design of a modern hospital included the orientation of the terrain, its relationship with the alignment of the rooms, and variations in designs according to the geographic area due to climate. In the context of the southern hemisphere, the hospital should ideally be positioned facing north, and similarly, the rooms should be oriented to the north to maximise natural lighting.[8]

Urban configurations and appearances of modern hospitals reflect inherent considerations of increasingly complex programmes, successive redefinitions, and the gradual incorporation of services, equipment, and technologies. The design of hospital complexes is influenced by intellectual processes, strategies, and compositional decisions. Among other factors, their urban locations play a key role in the final definition of their organisation, scale, and volumetric composition.

For Fortier, the hospital would be one of the first urban facilities.[9] In this sense, Fourquet and Murard argued that collective facilities reflected urban planning disputes and constituted the "skeleton of urban space." Furthermore, they proposed a spectrum of functions, derived from the Athens Charter, which materialised in collective facilities, among which "caring," translated into hospital and healthcare facilities.[10]

To study hospital complexes as urban projects, we must analyse the dialectical relationships between programmatic and formal resolutions and the urban positioning of healthcare establishments. This requires a systematic reading based on several factors: urban siting strategies, the relationships between programmes and architectural-urban composition, architectural accessibility operations, and contextual pre-existences and consolidations.[11]

3. THE MODERN HOSPITAL

The modern hospital configuration no longer requires large plots of land due to new construction techniques and scientific advances. Initially, it adopted the form of concentrated and vertical blocks, organised as complex healthcare systems that impacted upon urban organisations. However, within these complexes, typological variations can be identified, resulting from medical advances or technical and morphological innovations, which even led to lucid systemic compositions.

Throughout the 20th century, we have seen the configuration of hospital complexes designed to fulfil different healthcare functions or created

by incorporating new services into existing modern hospital buildings. These health complexes are urban enclaves with significant presence and prominence, around which large flows of people occur.

We observe the constant development of technologies for the treatment and cure of patients, which impact the hospital environment and can lead to the obsolescence of these buildings. As a result of this, many modern hospital buildings have been demolished or adapted for new functions. However, general hospitals, as they are large-scale complexes, show resilience in developing countries and continue to fulfil their social function through continuous adaptations. These hospitals occupy a significant place in cities as enclaves, and many of them are located near major transportation modes.

4. OBSOLESCENCE

Obsolescence is one of the factors affecting healthcare complexes and their considerations regarding modern healthcare heritage, as addressed in the session "The Modern Healthcare Architecture: Obsolescence and Transformation" at the 14th International Docomomo Conference in 2016.[12] Regarding this phenomenon, historian Daniel Abramson has questioned what happens when the function changes, aiming to detect what strategies have been employed to prevent obsolescence. An exemplary case was the design by John Week with Richard Llewelyn Davies for the enormous Northwick Park Hospital, formulated so that it could grow to avoid becoming obsolete.[13] The hospital was designed to have "growing limits" that could be continually transformed, ensuring there was never a "final plan" and that it remained "eternally unfinished."[14]

Week, in a study titled "Flexibility and Growth," concluded that hospital rooms should be "like branches on a tree, each with the freedom to grow without disturbing the general pattern."[15]

Abramson identified that the design logics of industrial warehouses had been adapted to laboratories and hospitals, consisting of stacked floors, some of which were completely cleared to accommodate programme spaces, alternating with thick intermediate levels housing facilities. This approach was applied in Louis Kahn's pioneering Salk Institute from 1959-1965 and in Charles Luckman's San Diego Veterans Administration Hospital in 1968. In this way, habitable floors were flexible and clear, in a system they termed "interstitial," to "create space that does not become obsolete."[16]

In the Chilean context, we have verified that hospital complexes designed since the late 1960s by the SCEH (or The Society for the Construction of Hospital Facilities, as it would be known in English) utilised certain strategies to accommodate evolving requirements over time, such as phased growth, as seen in the case of the Juan Noé Hospital in Arica, designed by architect Eduardo Vásquez in 1967 and completed in 1977.[17] Additionally, they employed three-dimensional frameworks, as seen in the case of the San Pablo Hospital in Coquimbo (demolished), built between 1970 and 1975, designed by architect Hernán Aubert (**Fig. 1**).

These strategies can be effective in addressing obsolescence; however, when dealing with urban complexes, we encounter a situation similar to that which

affected pavilion hospitals: the need for extensive land expansion. In the case of structures inserted in urban areas, growth operations can be complex and could alter the conditions of fullness and emptiness, and even require the adaptation or replacement of other constructions within the context of these urban complexes.

5. URBAN FACTORS

In our research, we observed several cases of the clustering of health services and institutions, prompting the question: why does this happen? Large hospital facilities, such as general and specialty hospitals, especially public institutions near transportation hubs, tend to generate what we call the clustering phenomenon. This phenomenon attracts a range of services and other institutions that complement hospital functions, such as primary healthcare services, imaging services, clinics, and other activities, forming geographically identifiable spatial connections in cities.

Interestingly, in the cases studied, this initially happened without apparent planning but was later appropriated by large hospital facilities –both general and specialty hospitals– for the implementation of new services and institutions.

Unlike hospitals for diseases treated in isolation –such as leprosy, tuberculosis, and mental illnesses, which were planned to be located outside of central city areas– general hospitals and specialty hospitals for non-communicable diseases depend on transportation services for the movement of patients, healthcare workers, and supplies.

Over time, we have observed intentions for changes in environments, such as the preservation of the historic centre of Rio de Janeiro, which houses modern hospitals like the Municipal Souza Aguiar Hospital, designed by architect Ary Garcia Roza, and the Cancer Hospital, whose projects dialogue with the historical surroundings.[18] The Souza Aguiar Hospital Complex serves as a prime example of an enclave, situated on preserved land in the historic centre of Rio de Janeiro (**Fig. 2**). While the hospital and blood bank from the original project by Garcia Roza are reasonably preserved, other buildings have been added to the lot, such as the Maria Amélia Buarque de Hollanda Maternity Hospital.

Other changes, like the creation of urban highways or BRT (Bus Rapid Transit) systems, had a direct impact on sites. For instance, the Institute of Puericulture and Pediatrics (IPPMG) of UFRJ, designed by Jorge Moreira, lost many of its gardens, designed by Roberto Burle Marx, while the Curicica Sanatorium Complex, designed by Sergio Bernardes, faced drainage problems and there was a visual impact on the building's scale due to the construction of the BRT elevated highway. It also experienced the demolition of pavilions.

It is important to note the Lagoa Hospital in Rio de Janeiro, designed by Oscar Niemeyer and Hélio Uchôa, which, despite being well preserved and featuring gardens by landscapist Burle Marx, had an emergency pavilion added that was not designed by the original architects.

6. STRATEGIES

Regarding strategies for healthcare complexes, it is evident that in recent years, adaptive reuse has gained significant relevance. This approach often

involves repurposing or adaptation; however, it does not preclude the application of well-formulated and respectful extension ideas as well.

Pier Francesco Cherchi, in 2016, published the book "Typological Shift: Adaptive Reuse of Abandoned Historic Hospitals in Europe," which, while it does not focus on modern architecture, addresses a series of strategies that have been applied to heritage structures. He divides these strategies into three groups. The first of which is the "general approach to adaptive reuse," which includes conservation and minimal modification, conservation of the historic envelope, conservation of typological order, and technological modernisation. The second group addresses "typo-morphological variations," including juxtaposition, addition, insertion, and subtraction. Finally, the third group deals with the "design of open spaces," covering new connections with adjacent public spaces, the expansion of public space, spaces of collective use for culture and art, and the recovery and reuse of outdoor space.[19]

Although these operations focus more on the "artifact" than on the urban aspect, Cherchi observed that, in the face of the abandonment of historic centres and the consequent stripping of the functions of buildings in these

20. Cherchi, Typological Shift, 70-71.

areas, communities rediscover these forgotten enclaves and recognise the historical significance of these structures, perceiving them as opportunities for renewal. This renewed interest allows for the reintegration of these "frozen" parts into the city's network of urban relationships.[20]

7. QUESTIONING HOSPITAL HERITAGE

It is relevant to discuss the relationship of these modern healthcare complexes in contemporary cities, their historical origin, their current uses, and their futures in light of the changes facing cities across different global regions. As buildings are constantly readapted and expanded with new spaces, questions arise regarding their obsolescence and inadequate locations: How should we treat these modern legacies? Should we adapt them to the new times? Change their uses and functions and create new complexes elsewhere? Renew inherited models from the recent past? Or reconsider their relationship with the city and the urban environment?

These buildings are constantly undergoing readaptation and expansion, especially in developing countries. Despite this, many view them as obsolete, leading to questions about their urban placement. These structures not only tell various stories about how we approach health and urban planning but also serve a crucial social function by providing public services. They represent examples of resilience, whether by adopting new uses, inspiring new building designs, meeting contemporary requirements, or serving as historical testimonies.

However, this topic and the questions raised here remain open for further exploration, and research suggests several avenues for investigation. Firstly, there should be greater recognition of this modern legacy. Additionally, it would be beneficial to compile an inventory and analyse solutions aimed at adapting these buildings to new functions and utilizing modern technologies. Furthermore, understanding how these healthcare facilities are integrated into cities and interact with other urban services is essential. Lastly, exploring emerging trends in hospital projects, particularly those that revisit modern principles, could provide valuable insights. ■

BIOGRAPHY

Claudio Galeno-Ibaceta is an architect with a Master's and PhD in Theory and History of Architecture. His research focuses on the relationship between human body knowledge and architecture, particularly in northern Chile's healthcare facilities. He serves as Associate Professor at UCN's School of Architecture and directs the master's programme in Architecture in Arid Zones. As General Secretary of Docomomo Chile, he's been involved with Docomomo International since 2004. He's also a member of the Latin American Network of Hospital Architecture Historians and the Ibero-American Association of Urban History. Currently, he's engaged in research projects on historical and modern architecture in Chile.

Ana A. Amora holds a PhD from UFRJ and is an Associate Professor at FAU-UFRJ. She coordinates LabLugares Research Group focusing on healmemory places and Brazilian architects. Amora is a CNPq research fellow and a member of the Ibero-American Network of Researchers in the History of Hospital Architecture. She previously served as secretary of Docomomo-Rio and participated in HOMEWORK-2012 on hospital architecture. Amora has extensive teaching experience, and has directed projects like the Health Cultural Heritage Inventory in Santa Catarina, and co-organised the book "History of Health in Santa Catarina." She published "Modernity in Hospital Architecture" and numerous articles on hospital architecture and modern architecture.

THE POWER OF ADAPTATION: THE CONVERTION OF A TEACHING HOSPITAL INTO A JUSTICE COMPLEX

IVO GIROTO
FACULDADE DE ARQUITETURA E URBANISMO - UNIVERSIDADE DE SÃO PAULO

ABSTRACT

This article analyses the conversion of a big hospital and teaching complex, developed between 1971 and 1978 and commissioned by Santa Casa de Misericórdia de São Paulo to a team of architects led by Fábio Moura Penteado, into the biggest criminal justice complex in Latin America, opened in 2000. The architectural characteristics and the superlative scale of the complex constitute a privileged object to analyze the potentialities and limits of architectural flexibility, as well as how this concept is related to the modern project culture, specifically with the general strategies developed by the so-called Escola Paulista.

1. INTRODUCTION

Terms like flexibility and related concepts such as multi-purpose adaptability, and multifunctionality were introduced and popularized by architectural modernity and, as such, have already been broadly discussed and criticized. However, it is worth revisiting them since the conservation of buildings from the past depends primarily on their ability to adapt to social transformations, changes in use, and new technological requirements.

In this context, the degree of complexity reached by certain programs, such as a hospital, induced certain morphological solutions and functional strategies in response to highly specialized medical, sanitary, and technological requirements, which at the same time need to accommodate adaptability and standardization to meet the constant demands for reorganization and expansion.

The project of the teaching hospital of the Santa Casa de Misericórdia de São Paulo, later converted into a criminal justice complex constitutes a privileged object to analyse the potentialities and limits of flexibility in architecture and how this concept relates to the modern design culture, more specifically to the strategies developed by the so-called Escola Paulista. It is also possible to question the place and type of expected flexibility in structures of gigantic scale, in which the technical demands aggregate onto others, related to the efficiency and capacity to support a high flow of users and the need to adapt to the Brazilian socio-cultural conditions.

The hospital complex project, developed by a team of architects led by Fábio Moura Penteado (1929-2011), started in 1968 and had its final version presented in 1978. After the construction of the concrete superstructure, a rectangle measuring approximately 240 m by 180 m, the project was paralyzed due to a lack of resources. More than a decade later, it was acquired by the State of São Paulo government to instate the Fórum Criminal Ministro Mário Guimarães, inaugurated in 2000, with the adaptation project by Borelli & Merigo Architects **(Fig. 1)**.

The initial project intended to build a complex of approximately 100,000 m² on a large plot of 240,000 m² on the banks of the Tietê River, a region close to the north side of the city centre of São Paulo and a strategic point of access to the city. In addition to having almost 800 beds and clinics capable of serving 4,500 daily consultations, it would have a medical school with 600 places and a training course for 3,000 health technicians, which would total an approximate flow of 15,000 people per day–between doctors, patients, students, staff, and visitors.[1]

It is important to emphasize that the concept of a modern hospital in Brazil was forged in strong dialogue with engineering and architecture, as evidenced by the work of architects like Jorge Machado Moreira, Álvaro Vital Brasil, and Rino Levi. Discussions held in institutions from São Paulo and Rio de Janeiro contributed to deepening the debate, such as the Hospital Organization Division DOH (1941), led by medical doctor and engineer Ernesto de Souza Campos, and the Hospital Research Institute IPH (1954), whose founder and first president was the architect-engineer Jarbas Karman.[2] Among others, both

2. Ernesto de Souza Campos (1882-1970) was an interlocutor of the Rockefeller Foundation in Brazil and one of the founders of the University of São Paulo Medicine School and Minister of Education and Health in 1946. Jarbas Karman (1917-2008) worked at the Special Public Health Service – SESP, established in 1942 which marked the beginning of cooperation between Brazil and the United States in the field of health.

helped to stimulate the debate about the design and construction of hospitals, in close relationship with experiences developed in the United States.[3]

In the context of the work's conception, the rapid population growth of the São Paulo metropolis cannot be disregarded, whose cities went from 8,139,730 inhabitants in 1970 to 12,588,725 inhabitants in 1980,[4] driven by strong internal migration, mainly of people from the northeast region of Brazil, in search of better living and working conditions in the most industrialized city in the country.

No less superlative than the teaching hospital, the criminal justice complex that took its place decades later houses almost all the criminal justice facilities of the São Paulo metropolis and constitutes the largest of its kind in Latin America. Its facilities house 31 criminal courts, a prison for 400 inmates, and several other courts, departments, and sectors of the city's judiciary system. With an average daily flow of 5,000 people, around 1,400 employees and more than 100 magistrates work at the justice complex.[5]

2. FROM HOSPITAL TO JUSTICE COMPLEX

In the late 1970s, the charitable institution Santa Casa de Misericórdia de São Paulo began to implement a project that had been put on hold since 1963 to create a modern teaching hospital, destined to serve a contingent of about 1 million people in a situation of "absolute poverty", in the words of Penteado.[6]

The proposal presupposed a profound institutional renovation, joining the concept of a teaching hospital with that of a general hospital, according to Teófilo de Almeida[7], "one that receives all or several types of patients with different diseases" and, therefore, required high levels of training of the technical staff, treatment techniques, equipment, and care with safety and contagion that also resulted in specific requirements for spatial organization.

The existing documentation in Penteado's collection records four different preliminary designs of the project, developed since 1968. In these previous designs, it becomes clear a general solution by wings interspersed with landscaped courtyards and connected by a central strip, surrounded by a continuous lateral surface of exposed concrete that demarcates a single volume.[8]

In the definitive proposal, an offshoot of the latter from 1978[9], Penteado and his team presented a solution that offered the identity that previous generic solutions lacked. The building's program would be distributed on three main floors—a basement, the ground floor, and the upper floor, in addition to a technical floor—and in three functional strips in the plane—two sides, cut by open patios on the roof, and a central section with the main function of distributing the flows. It is a tripartite organization that reflects on the facades, characterized by three large lowered arches that, on two sides, coincide with the functional strips and, on the other two, with the centres of the garden patios.

The crucial difference of this last proposal lies in the idealization of a square-gardened central square, arranged in the central strip close to the main access to the building. On the ground floor, from the corners of the

square, four ramps start at an intermediate level, from where four others go up to the upper floor **(Fig. 2).**

The option for a large horizontal building was opposed by the "podium on a platform" typology, vertical and hermetic; a centralized model was generally considered more efficient. According to Renato Gama-Rosa Costa[10], the monoblock system, created in the USA in the first decades of the 20th century, attracted the attention of more and more Brazilian hospital planners and would achieve hegemony in the country after the 1950s, in part due to the great dedication from architects to projects that would increasingly employ high technology. Also, the demand for large plots of land for implantation, increasingly scarce and peripheral, seemed to indicate the vertical solution as the most appropriate.

However, Penteado's project combined the typology in a single but horizontal block with the logic of pavilion spatial structuring, with the wings interspersed with open patios. But if medical and surgical processes came to be considered virtually deterministic as regards building form, putting typology in strict relation to the functionality and flexibility of the building, why, then, would Penteado opt for an immense horizontal hospital with paths that could reach 200 meters of extension?

An answer may lie at the crossroads of several questions and conditions. First, and the most obvious, is that there were no space restrictions for its implementation; on the contrary, the land was so wide that the architect foresaw a series of buildings and additional programs, including the opening of a "Health Park" around the building, open to the public.

Second is in the design tradition of the so-called "Escola Paulista", of which Penteado was an important part, alongside such greats as João Batista Vilanova Artigas (1915-1985) and Paulo Mendes da Rocha (1928-2021). In the architectural repertoire of many members of this generation, buildings of marked horizontality prevailed, functionally and plastically resolved by the definition of generic grid roofs, under which the program of needs was freely articulated, surrounded by relatively continuous and blind facades in exposed concrete.

A third possible reason is directly related to the second. The idealization of the internal space as an infrastructural prototype and urbanity metaphor, a thought common to the "brutalist" architects of São Paulo, which, in Penteado's work, took on meanings that went beyond public suggestion to reach the individual dimension of the most disadvantaged inhabitants of the metropolis. In this way, the idealization of interiors that emulate a system of streets and a central square sought to configure the familiar spatiality of a small town with an open and spontaneous character to facilitate internal orientation **(Fig. 3)**.

A decade before the beginning of Penteado's project, Jarbas Karman[11] highlighted that regardless of the typology adopted, what is important is to design an efficient scheme concerning the optimization of the routes by nursing professionals, whose lengthening would result in greater physical wear and tear and financial burden, as "each step weighs and costs".

10. Renato Gama-Rosa Costa, "Apontamentos para a arquitetura hospitalar no Brasil: entre o tradicional e o moderno," *História Ciências Saúde-Manguinhos*, n. 18 (December 2011).

11. Jarbas Karman, "o hospital bem planejado" (1958), in *Monica Mussati Cytrynowicz, Instituto de pesquisas hospitalares arquiteto Jarbas Karman* (São Paulo, Narrativa Um, 2014), 90-91.

In addition to efficiency issues, Penteado considered the vertical solution wrong for the Brazilian conditions. As a "crowd hospital", he defends the dilution of traffic flows through the ramps and internal streets, loaded by the presence of many visitors, a problem that he did not consider relevant in European and American hospitals.[12]

As for the questions about the efficiency of the circulation and distribution of hospital services, Penteado[13] mentions the carrying out of "research to rationalize the movements, carried out in conjunction with the Santa Casa de Misericórdia hospital consultancy", whose tests were carried out "by pushing carts with a stopwatch on the hand", demonstrating that only 4 minutes separated the most distant points of the building. The diagonal arrangement of the four ramps that are in the center of the square would avoid peripheral routes through the wings, shortening them.

Research shows estimates that, at the peak of the "podium on a platform" typology, nurses spent 40% of their time in patient transport logistics mostly because circulation patterns were confusing, without any external cues of directionality, setting, or hierarchy, which indicates that not only the distances should be considered for the optimization of the routes.[14]

As Jonathan Hughes[15] notes, obsessive attention to the physical separation of functions and traffic flows in hospital environments, in addition to satisfying specific needs, reveals a recurring association between clinical and civic design during the last century, when hygiene started to support discourses defined by health, efficiency and speed criteria, with an emphasis on the circulatory system. Thus, the hospital was not only the place of medical interventions but also linked to the city as a way of testing planning techniques like those of modern urbanism.

In the mid-1990s, with the large concrete structure in a state of disrepair, the government of the State of São Paulo acquired the area and resumed the construction. The project to convert the hospital into a criminal justice complex was carried out by architects José Borelli Neto and Hércules Merigo on the recommendation of Fábio Penteado himself, with whom recent graduates had worked on the detailing of the teaching hospital project.

In summary, the hospital project intended for the ground floor to be the main entrance for users and various administrative sectors, in addition to reserving one of the three functional lanes for outpatient clinics. The first floor houses similar functions, with the difference that this floor contains several public service rooms and institutional headquarters. On the upper floor would be the hospital's "critical area", intended for hospitalizations and surgeries, pediatrics, and nursery, in addition to the Intensive Care Unit. In the justice building, the courtrooms (up to 52) were concentrated on this floor, designed in modules that adapt to the original structure and circulation.

The hospital's complementary services—changing rooms, storage, warehouses, and other technical support spaces—would be located at the basement level, which would also house the emergency unit, food sectors, and an auditorium for 250 people. In the justice complex, the support and

food structures were kept, the auditorium is used for the plenary sessions of the jury, and the emergency sector was converted into a prison.

3. SUMMARY

Although, obviously, the new use required design adjustments, there were no major changes in the spatial or formal structure of the building. The conservation of its original architecture seems to be mainly due to the multipurpose structuring scheme of functions and circulations. Borelli and Merigo reiterate the validity of the internal organization from an urbanistic view, where the different scales of "avenues and streets" create a spatial hierarchy that facilitates orientation.[16]

Furthermore, the development of an open-ended project would provide sufficient flexibility for installations or relocation of sectors in the building. Even with a different use, it can be stated that the structure meets the new functional demands well. The established São Paulo strategy

of idealizing large covered spaces certainly helps. Effectively, it is not difficult to imagine the conversion of space, without great difficulties, to several large projects, such as a shopping center or a university.

The drawings of the definitive version reveal that the project did not start from forms strictly defined by functions; on the contrary, it previously defined a flexible and virtually expandable formal-functional scheme. However, it is not a merely generic building, especially due to the conception of a network of circulations that transcends its functional destination by defining the central square as a symbolic and hierarchical anchor of its interior (Fig. 4).

Similarly, it manages to avoid the side effects that Hertzberger[17] identified in the obsessive search for eminently functionalist flexibility, which, when trying to adapt to all kinds of changes, ends up not meeting any in an ideal manner. In his well-known analyses, the Dutch structuralist defended the adoption of multipurpose forms, which lend themselves to different uses without the need to undergo major changes or lose their identity.

In their definition of adaptable design, Rabeneck, Sheppard, and Town[18] defended the idealization of environments with generous dimensions and similar proportions, adaptable to a change of furniture and light partitions, avoiding the need for large infrastructural works. Based on research on historic residential buildings, they found that, as in the Penteado project, the possibilities of adaptation are facilitated by the presence of a central coordinating courtyard or hall, without fixed functions, surrounded by environments without major hierarchical differences or fixed furniture.

It is worth noting that the conception of flexible architecture, when guided by a narrow functionalist view, often mistakenly equates uses to users, and functions to people, which ends up frustrating—in Lefebvre's words, "the very possibility of multi-functionality."[19]

The complex's quality and value for the architectural culture of São Paulo was recognized by the CONPRESP (Municipal Council for the Preservation of Historical, Cultural, and Environmental Heritage of the City of São Paulo) on February 12th, 2018, regardless of the change in its original function. ■

PAIMIO SANATORIUM—THE MASTERPIECE IN CHANGE

#06

JONAS MALMBERG
ALVAR AALTO FOUNDATION / AALTO UNIVERSITY

ABSTRACT

The paper concentrates on the reuse of an iconic modernist building and adaptation of a Conservation Management Plan in use. In the case study of Paimio Sanatorium, the strong protection stipulations as a national monument from 1993 may simultaneously restrict potential uses and be insufficient to protect the values.

The building had since the construction became an architectural sight. Even Aalto himself took his friends to the site. When completed the building was widely published internationally. Possible uses are to be such that the values of the entity are preserved and also visitors' needs can be sufficiently met. Yet, the rather remote location in Paimio city, Southwestern Finland, and considerable size of the complex results in the reality that at least current flow of visitors can't provide income sufficient for the maintenance and heating.

At the same time, it seems unlikely that the hospital uses would return. Contrary the contemporary hospitals include extremely specific requirements and facilities which are very difficult to adapt in a protected building without heavily compromise the preservation.

The premises were nominated as a national landmark in 1993. At that time no other possible futures than the ever-continuing hospital use was taken into an account. Indeed, the use was written in the stipulations. However, the last ward moved out in 2015. Consideration what kind of layers should be preserved from the first 90 years ought to be taken into an account as new uses are designed.

1. INTRODUCTION

The building completed in 1933 as Paimio Sanatorium was of key importance to the international career of architects Alvar and Aino Aalto, whose groundbreaking entry won the competition in 1929. The entire building complex, grouped together in several buildings according to use and orientation, was constructed in accordance with Aalto's philosophy, right down to the smallest details of the furniture and the lighting fixtures. According to the contemporary idea of standardization, these items were also planned for use elsewhere—for example, many pieces of the wooden furniture became key products for Artek founded two years later. Especially the chair 41, so-called Paimio chair, has become a design icon.

With the advent of antibiotics, tuberculosis could be cured. So, the sanatorium was gradually converted into a general hospital from the mid-1960s onwards. Gradually by 2015 all the hospital wards had moved to new premises erected in more accessible locations. Since 2021, only tourism and events, and exhibitions have remained in addition to some housing. Also, the owner of the site changed in 2020 as Paimio Sanatorium Foundation was established.

Current uses in the half empty premises are insufficient to provide stable economy for the site, whose annual maintenance and heating costs reach up to € 1.000.000—not including major interventions or restorations. New possibilities have been actively studied, but due to the size of the entity, rather remote location, and characteristics of the buildings it had turned out difficult. The location in the outskirts of a 10.000 inhabitants city Paimio in Southwestern Finland is distant and without large variety enterprises.

The fundamental question for the uses is that they would accept the location. Simultaneously they should ensure finance, and above all they must be able to fit into the site without major compromises on preservation.

2. PROTECTION

The value of the site had been understood and public discussion due the alterations was opened in the 1970s.[1] The protection as a national monument was approved in 1993. Through the Building Protection Act (60/1985) (Council of State decision no. 43/561/92, 18.3.1993), the protection of the Paimio Hospital encompasses the main hospital building, the former heating plant, the garage, the former staff housing, the former junior physicians' row house, the former chief physician's house and the funeral chapel, as well as the surrounding area.

The protection covers the exterior of the buildings, the original interiors, the building structures, the building parts and the remaining fixed furniture and fittings, including the original lamps and details. The protection stipulations also state that the protected buildings and their surroundings must be maintained and conserved in accordance with their architectural and cultural-historical value.

The justification for the decision to protect the building was that "Paimio Sanatorium and the residential and utility buildings is a national building monument of cultural-historical importance with regards to building history, architecture, building technology as well as its uniqueness."[2] The protection stipulations are:

1. Maima Norri, "Kuinka käy Paimion parantolan?," *Arkkitehti* 7 (1977): 15 (Helsinki, Finland: Association of Finnish Architects).

2. Nina Heikkonen (ed.), *Paimio Sanatorium Conservation Management Plan*, (Alvar Aalto Foundation, 2016), 213-4.

1. The exterior of the protected buildings must be preserved and in repairs original colours and surface treatments must be used.
2. The original interiors, structures, building parts, remaining fixed furnishings including original lamps and details of the hospital building, the former chief physician's residence, the junior physicians' row house and the funeral chapel must be preserved and the colours and the materials of the original designs must be used in repair work.
3. The protected buildings and their surroundings must be maintained and conserved in accordance with their architectural and cultural-historical value. The buildings must be used so that their cultural-historical value is not endangered, and their use must serve the hospital function or a function that is in concordance with the original activity. Any repair or alteration work must be in concordance with the architectural value of the site and approved by the Finnish Heritage Agency.[3]

2.1. ALVAR AALTO FOUNDATION AS A STAKEHOLDER

According to the protection stipulations, the Finnish Heritage Agency has to approve all repairs and alterations. The Agency is an expert body responsible for protection and restoration issues of the most valuable protected architectural heritage.

The specialized knowledge of the Aalto Foundation as the preserver of the architectural heritage by Aaltos' is also to be taken into an account. Since 1990s the Foundation has actively promoted preservation and protection, provided knowledge, archival services and specialized information.

In 2020 Alvar Aalto Foundation was nominated as one of Finland's 18 museums with national responsibility as T*he Museum with the national responsibility of Alvar Aalto's architecture and design heritage*. Thus, the foundation's status in restoration projects became refined more accurately than before. The role adds to the Foundation's cultural-environment duties tasks such as supervising restorations, coordinating planning and advising on repairs of Aalto sites as stipulated by law. Before the participation of the Foundation had no definition based on law but was merely voluntary.[4]

Currently in addition to Paimio Sanatorium 12 other Aalto sites are protected according to the strongest protection law and there are three ongoing protection processes: the Aalto Studio, the Experimental House and the National Pension's Institute building. Also, two churches by Aalto are protected on the Church Act (1054/1993) assigning an active role for the Finnish Heritage Agency in their preservation. Thus, contacts and co-operation between the Heritage Agency and Aalto Foundation is active and fluent providing possibilities for constructive discussion and mutual understanding.

2.2. CONSERVATION MANAGEMENT PLAN

Both Aalto Foundation and the various authorities have been well prepared for emerged questions due to the Conservation management plan (CMP) completed by Aalto Foundation in 2016 as part of the Getty Foundation's *Keeping it Modern initiative*.[5]

3. Heikkonen, *Paimio Sanatorium Conservation Management Plan*, 213-4.

4. "Alvar Aalto Foundation now National Special Museum for Alvar Aalto's Architecture and Design Heritage," Alvar Aalto Foundation, accessed May 1, 2024, Alvar Aalto Foundation now national special museum for Alvar Aalto's architecture and design heritage - Alvar Aalto Foundation | Alvar Aalto -säätiö EN.

5. "Keeping it Modern," Getty Foundation, accessed April 9, 2024, https://www.getty.edu/projects/keeping-it-modern/.

The current protection stipulations still leave possibilities for discussion and refining the details. In the CMP preservation goals became discussed in depth. The CMP has no legal status, but it provides thoroughly considered possibilities for interpretation. The advisory board nominated for the process included representatives from all legal stakeholders. At that time completely revising the stipulations was not found necessary.

The question of originality in the main entrance lobby, for example, was proposed be refined meaning the status which was realized in 1958 following the design by Alvar Aalto's office. Originality was considered to refer to the original sanatorium use, whose end can be dated to the mid-1960s. In 1965 new law was assigned allowing also other than tuberculosis patients to be treated in the state subsidized public sanatoria and two years later another new law allowed the tuberculosis districts to be combined into health care districts. The tuberculosis was defeated due to improved medicines and broad coverage of vaccinations. Then the first reuse as hospitals took place in most of the sanatoria in Finland, including Paimio as discussed in the DOCOMOMO Lisbon conference in 2016.[6]

3. OBSOLETE PROTECTION STIPULATIONS

According to the current legislation the protection stipulations of a national monument can't be revised unless the whole protection is reconsidered.

Current stipulations are written in a way which allows flexibility to facilitate the continually improving hospital uses. Simultaneously they set the Finnish Heritage Agency a very strong position compared to more contemporary orders on other sites. The process of renegotiation new stipulations may result that the new ones may not become as strong or comprehensive as the current ones, which are not limited to certain parts of the interiors. Such flexibility is no longer allowed in the contemporary stipulations approved by the Governmental Centre for Economic Development, Transport and the Environment.[7]

In the early 1990s when the protection of Paimio Hospital was prepared the building history was not studied and evaluated in a contemporary way. The aspiration of returning to the idealized 1930s status was evident. As a detail for both the exterior and interior is assigned that "the colours and the materials of the original designs must be used". The building technique has significantly changed and returning to the original paints mixed on the site, for example, is not reasonable.

In the current situation consideration whether some layers of the hospital use ought to remain if a comprehensive reuse takes place. Some of the alterations of the main building as well as the staff housing, all designed in Aalto's office in the 1950s and 1960s may also include architectural and historical values. Yet, the current stipulations do not recognize their qualities.

If new stipulations were to be written the procedure of hearing of the current owner and other stakeholders would take place, and the in all it would take some years—longer than the span of solving the current issues of the half-empty site should take.

7. "Protection under the Act on the Protection of the Built Heritage," Finnish Heritage Agency, accessed April 9, 2024, https://www.museovirasto.fi/en/cultural-environment/built-cultural-environment/protection-under-the-act-on-the-protection-of-the-built-heritage.

4. NEW OWNER AND USES

Since the CMP even the owner has changed. The memorandum of the Paimio Sanatorium Foundation was signed on 27 October 2020 by previous owner the Hospital District of Southwest Finland and, the State of Finland, the Alvar Aalto Foundation, the Municipality of Paimio, and the City of Turku.[8]

On contrary, the idea of ever-continuing use as a hospital is strongly stated in the protection goals from the early 1990s. Furthermore, the use is assigned in the stipulations to "the hospital function or a function that is in concordance with the original activity". The latter may be flexibly interpretated but still, could for example a hotel, spa or tourism and leisure activities fit in the description?

The owner has indeed launched the design process to convert the uses of the site. Ideas involve several purposes including hotel functions in the main building.

4.1. HEALTHCARE?

Currently it seems unlikely that hospital functions could return. During the last decades the demands in hospital uses have become more and more detailed and complicated, and more challenging to be accommodated in old buildings. Simultaneously new hospital premises have been built in the region in logistically more convenient locations. Contemporary highly specialized large hospital in Paimio would be impractical even without having to balance with the architectural preservation.

The latest use as a children rehabilitation was well in balance with the original activities. Also, users were satisfied and inspired on the modernist architecture. Approximately half of the building stock was accommodated by the rehabilitation services but supplementing operators weren't found. Furthermore, economical competition in the rehabilitation sector turned out to be intensive and the operation became too expensive there. Unfortunately, it was discontinued in 2021.

4.2. HOTEL OR ACCOMMODATION?

The owner has launched a preliminary design process to convert the uses of the site to include several purposes including hotel functions in the main building.

Paimio Sanatorium has more than a hundred relatively equal sized rooms whose dimensions meet those of a modest hotel room. The layout may indeed remind that of a hotel. Sanatoria a century ago in Switzerland, for example, reminded hotels, as can be familiarised in Thomas Mann's iconic novel *Magic Mountain*. Paimio Sanatorium has become a tourist attraction since the beginning. Could these be conveniently combined as a hotel. At the current light, it seems to most probable solution to be studied further.

Questions may rise in a more detailed observation. Currently, the patient rooms have neither individual bathrooms nor toilets. Most of them are in the late 1970s appearance designed by Aalto's office. What kind of conversion would be reasonable?

8. "Paimio Sanatorium Foundation," Paimio Sanatorium Foundation, accessed April 9, 2024, https://paimiosanatorium.com/sanatorium/foundation/.

According to contemporary building legislation, in a re-use the current standards for a new construction should usually be met. That applies to fire protection and sound proofing for example. It opens up a variety of questions to be studied in depth.

Also, some current 50-year-old hospital style durable materials like the vinyl floors witness the second period as a hospital. Originally most of the floors were carpeted with linoleum. Neither of those remind a contemporary quality hotel interior. Replacing any material, even with those reminding the original solutions results in losing authentic hospital layers.

Which kind of uses could be in other parts of the building, where for example spa or saunas would be located? To some extent the large complex provides a variety of possibilities. Parts of the basements have been refurbished over the years several times. Also, the interiors of the 1958 completed surgery wing have been completely rebuilt a few times, the last refurbishment took place as late as in 2005. With careful design these spaces among others provide flexibility as discussed in the CMP.

Yet the major question in the long run is the balance between protection and refurbishment. Are visitors also in the distant future willing to come to the rather remote site for the hotel, which itself would be the main sight, but may have an appearance resulting from a relatively recent refurbishment?

Could possibility to experience a tuberculosis sanatorium with only little comforts be adequate? Some other uses instead of a hotel might result in harmonious continuity with the original healthcare as did the children rehabilitation. Unfortunately, if these were easily found they would have been introduced within the last ten years.

The process has started, and several decisions are to be answered soon. Many questions can be solved with careful design. Yet, every alteration means losing some layers from the history and authentic material. Any current material, even reminding the original is still not authentic.

4.3. THE PROCESS AND UNESCO WORLD HERITAGE

The State of Finland submitted a renewed tentative for the UNESCO World Heritage in 2021 including a group of Aalto buildings.[9] Naturally Paimio Sanatorium is included.

Issue of authenticity and the continuous use as a hospital were fundamental ideas in the earlier nomination process in which Paimio Hospital was alone in the tentative list since 2004.[10]

How much can now be sacrificed in order to provide uses for the site without compromising the outstanding universal value of the World Heritage?

5. CONCLUSION

Protection stipulations are made difficult to change on purpose. Their fundamental goal is to be effective in the long run. There are values that should not alter. At the same time the regulations are bearing ideas from the time they were assigned.

9. "The Architectural Works of Alvar Aalto - a Human Dimension to the Modern Movement," UNESCO World Heritage Convention, accessed April 17, 2024, https://whc.unesco.org/en/tentativelists/6509/.

In the case of Paimio some principles drastically changed as it became evident that hospital uses will not continue. Simultaneously, current thinking in preservation is recognizing also layers of various periods in a stronger way than was found necessary more than 30 years ago.

Balancing in the aims of preservation and flexibility in uses is difficult. In an ideal case any alteration should to improve the quality of the protected built environment also in the long run. On the other hand, even as well-known architectural monument like the Paimio Sanatorium can't be kept without sufficient funds. Currently continuous subsidy from the state or other stable sources can't be seen as a solution without a proper use all year around. More questions are topical than exact answers.

Both the owner and other stakeholders, including the designing architects are facing the problems to solve. The answers may vary depending on the point of view. How the complex can simultaneously be a milestone monument in the history of modern architecture and an active place of various uses–globally thinking in the middle of nowhere. ■

OBSOLESCENCE AND VULNERABILITY OF MODERN HOSPITAL HERITAGE. THE CHALLENGE OF RURAL PSYCHIATRIC HOSPITALS IN MEXICO

#06

IVAN SAN MARTÍN CÓRDOVA
UNIVERSIDAD NACIONAL AUTÓNOMA DE MÉXICO

ABSTRACT

Modern hospitals around the world impacted urban environments, whether they were small works or large health complexes. However, there have also been illnesses that necessitated geographical isolation due to the specific nature of the diseases, requiring distance and seclusion to promote health benefits.

Iconic examples of this type of facility were the tuberculosis sanatoriums, leprosarias (or leper colonies as they are known in English) or hospitals for mental illnesses, which had to be built outside traditional urban settings, the first two for fear of contagion and the third, under the model of "rural hospitals", in response to the psychiatric theories that recommended urban isolation at the time.

In Mexico, several psychiatric facilities were built under this model in the mid-twentieth century. Their authors designed large hospital complexes outside the cities, which made it necessary for them to include living quarters for the health personnel, as well as spaces for physical or mental recreation for the patients. However, at the end of the 20th century, new psychiatric theories took a clinical turn, recommending the patient's closeness to their social and family environment, which has transformed their original sense of isolation and places them at risk of patrimonial vulnerability. From some case studies in Mexico City, this model will be identified using a methodology based on consulting institutional archives and visiting psychiatric facilities to identify the characteristics of this vulnerable hospital heritage. It is expected that the result obtained will be a reflection on how to rethink its relationship with the contemporary city.

1. INTRODUCTION

In Western modernity, hospitals - and also prisons - ceased to be conceived as places of perpetual confinement to give way to scientific establishments where it was possible to heal their patients - "machines for healing," as Michael Foucault would say - and subsequently reincorporate them into society.

In the first decades of the 20th century, the compositional schemes were symmetrical, and their morphologies still reflected the inertia of historicism; however, with the advent of the Modern Movement, hospital complexes adopted steel and concrete structures that allowed for greater flexibility and ventilation of the spaces.

2. DISTANCE FROM CONTAGION

Due to the clinical characteristics of some diseases, it was recommended to locate them far from urban areas, either to minimise the possible spread of the causative agents, or to alleviate the impact on the immediate family and social environment. In the first instance, we can make reference to the tuberculosis hospitals, such as the world-renowned tuberculosis sanatorium in Finland, whose geographical remoteness was considered indispensable in correspondence for the bacterial treatments available at that time since penicillin would not be discovered by the Scotsman Alexander Fleming until the mid-twentieth century.

These medical scenarios in Mexico were no exception. In the hospital complexes far from urban centres, leper colonies and homes for the insane, as those facilities were called at the time, had existed for centuries. With the consolidation of hygienist thought in the 19th and early 20th centuries, these places ceased to be places of perpetual confinement and began to be attended to in a more scientific manner. Thus, the first modern hospitals were built away from the urban sprawl to try to heal and reincorporate patients into social life, some served to reduce contagion, while others would isolate the patient from his or her environment.

Among the first, the Sanatorium for Tuberculosis Patients in Huipulco, a small town far from the Mexican capital, was built on a spacious site that allowed for isolation and ideal ventilation for the patients in the 180 beds it initially housed.[1] This public building was constructed between 1929-35 under the design of architect José Villagrán García. This design adopts the guidelines of the Modern Movement, both through the use of the reinforced concrete and in the morphological sobriety, although it still presented a symmetrical composition in the set and the presence of geometric ornaments.

In order to reduce the spread of leprosy, the Mexican government set up a series of public clinics close to the most affected geographic regions in the first decades, in order to provide a first level of care, while for the most advanced cases of Hansen's disease, the Zoquiapan hospital was built in 1939, on the side of the highway that linked the Aztec capital with the nearby city of Puebla. It was a complex where patients could reside

1. Xóchitl Martínez-Barbosa and José Villalvazo-Reyes, "Huipulco Tuberculosis Sanatorium in its first ten years of operation," *Revista CONAMED*, *Vol*. 22 (2017): 31.

permanently, and were assigned a plot of land for growing vegetables and keeping domestic animals.

3. THE DISTANCE FROM THE MENTAL DISORDER

Psychiatric hospitals required varying degrees of isolation, whether for outpatient care as needed for patients experiencing occasional crises and receiving regular therapy or for those whose mental disorder required radical separation from their home environment. In the first scenario, patients could be treated in urban hospitals, while if the diagnosis was serious, they were required to be housed in health complexes with different characteristics from urban hospitals.

In Mexico, since the beginning of the 20th century, the country's main cities had asylums, as they were called at the time, located outside the urban centres or in the vicinity of small towns where the families of medical personnel and health employees used to live. In the case of Mexico City, in 1910 the "La Castañeda" General Asylum was built, an hour's drive from the capital, where mental patients were classified and separated. It was not until 1965 when President Gustavo Díaz Ordaz made the decision to close and demolish it, since the old building no longer served to apply psychiatric treatments, which made it advisable to divide the levels of care: a first level of psychological services in neighbourhood clinics, a second level inside general hospitals, and a third level in high-specialty hospitals. Therefore, an ambitious government program was proposed to build two types of tertiary mental hospitals: those in an urban area, for children and adult patients, and those in rural areas, built solely for men and women in adulthood.[2]

3.1. URBAN PSYCHIATRIC HOSPITALS IN MEXICO CITY

To provide psychiatric care in urban areas, two new modern facilities were built in the south of the city: the "Dr. Juan N. Navarro" children's hospital (1966) with 200 beds for infants and adolescents with mental disorders and the "Fray Bernardino Álvarez" hospital (1967) with 616 beds for acute adult patients. In both cases, these were tertiary-level hospitals that treated patients on an outpatient basis and only, if necessary, admitted patients for short stays of a maximum of ten weeks.[3] The buildings were constructed by the Secretaría de Salubridad y Asistencia (Ministry of Health and Assistance), a ministry under the presidential power. The designs were commissioned to Joaquín Álvarez Ordóñez, a Mexican architect born in 1932, who was then director of the office in charge of sanitary equipment.[4]

The "Dr. Juan N. Navarro" Children's Psychiatric Hospital was directed towards child and adolescent patients, a sector that had already been attended to in previous decades, but from a ward within a larger hospital, either as part of a hospital for the insane in general, or in a sector within a children's hospital.[5] On a vast plot of land, several bays were built and interconnected by covered walkways. The remainder of the property was

made up of arranged courtyards with porches for visitors and gardens with playgrounds for the physical and mental well-being of the patients.

The other urban hospital was the "Fray Bernardino Álvarez" Psychiatric Hospital, located just across the street from the aforementioned children's hospital. It was designed as the primary centre for all public mental health care in the capital, serving both adult patients and those referred to one of the other hospitals in the network based on the recommended treatment.[6] A ten-story tower was chosen to house the hospitalization, outpatient clinic, pharmacy, laboratories, operating theatre and intensive care, as well as an area for research and prevention of mental disorders, while the hospitalization area had medical and nursing staff, psychologists, and social workers, as well as service areas. The first floor had areas for occupational therapy with activities such as sewing, pyrography and wool rug manufacturing.[7]

3.2. RURAL PSYCHIATRIC FACILITIES IN MEXICO CITY

The "rural hospital" model - also called "farm hospital" - responded to the psychiatric trends of the first half of the 20th century. It was thought that acute mental disorders would improve if patients lived in isolation and with plenty of green spaces - replacing the quasi-prison system of the previous psychiatric hospitals - for recreation and for agricultural work carried out by the patients themselves, whether it was the cultivation of fruit trees, vegetable gardens and keeping of animals - for those who were able to do so - to promote the patients' gradual return to mental health. In Mexico, this model had already been applied since the 1940s, but in adapted buildings, which provided an opportunity to design modern complexes that were more efficient and sufficiently removed from the urban environment.[8]

During that time, four hospitals were built in accordance with the rural model, two completely new and two within existing buildings. For the two new modern sets, the clinical molding of pavilions was recovered:[9] 1) the "Samuel Ramírez Moreno" rural facility (1967) with 529 beds for male patients with the possibility of rehabilitation, in Tláhuac, in the east of the Mexico City; 2) the campestre "Dr. Adolfo M. Nieto" (1968) with 529 beds for patients with the possibility of rehabilitation, in Tepexpan, north of the city; the other two were: 3) the "Dr. Rafael Serrano" (1967) with 505 beds for chronically ill patients with the possibility of rehabilitation, near the city of Puebla; and, 4) the rural "Dr. Fernando Ocaranza" (1966) with 636 beds for chronically ill patients with a difficult rehabilitation scenario, in the neighbouring state of Hidalgo.[10]

The "Dr. Samuel Ramirez Moreno" Hospital was built on a plot of land in excess of 20 hectares. The layout consisted of isolated pavilions, each corresponding to the severity of the disease. In the centre, there were the auditorium, the dining room and the kitchens surrounded by a square and covered walkways -straight and curved- leading to the dormitory pavillions. The most striking feature was the auditorium roof: a hyperboloid with a lower section larger than the upper one and topped with a skylight. The

roof itself was made of reinforced concrete that extended to ground level to serve as its own support.

In contrast, the Hospital Campestre (Rural Hospital, as it it known in English) "Dr. Adolfo M. Nieto" was built to accommodate adult patients with acute disorders. The overall layout adopted a concentric scheme, with a central circular plaza and pavilions with circular volumes. The architectural programme considered plans for five different areas: 1) the entrance building including outpatient offices, consulting rooms, intensive care beds, laboratories and social work facilities; 2) the hospitalization area divided into four wards, each with 112 beds, sanitary services, a nurses' station, and a restricted section for inmates with mental disorders; 3) general areas made up of a dining room, occupational therapy rooms for embroidery, sewing, drawing, beauty, modelling and relaxation rooms with televisions, board games, and spaces for reading, and finally, there was an auditorium for watching movies and performances; 4) the characteristic feature of this model included farms for therapeutic work with animals such as chickens, rabbits, sheep and pigs. Additionally, it featured sports courts for basketball and volleyball, as well as extensive gardens; 5) general services included the kitchen and laundry areas, power house, boiler house, substation, warehouse, workshops and elevated water tank, as well as areas for employees such as bathrooms and dressing rooms, and finally, living quarters for the doctors, considering the director and administrator, as well as dormitories for the residents. The remainder of the employees were external.

Seen from a distance, they looked like small impregnable villas where patients lived for years and decades, and sometimes until the end of their days, as it was common for family members to abandon them.

4. FINAL CONSIDERATION

Those urban or rural psychiatric hospitals continue to operate six decades after their construction, although they have had to adapt to the transformations driven by the new medical theories of mental disorders that favour the short-stay clinical model, in other words, providing asylum to patients for days or a couple of weeks, instead of uprooting them for years or decades from their psychosocial environment. In addition, advances in neurological and neuropsychiatric research have changed the clinical landscape, and as a result, punishment procedures that did not result in improvement but did violate the human rights of inmates have been eliminated.

In recent years, the trend in Mexico has been to build general hospitals that include a section for mental disorders, instead of exclusively psychiatric hospitals, which has had an impact on the future of these hospital complexes, as it puts them at risk of asset vulnerability. In the case of rural hospitals, the majority of them have been overtaken by urban sprawl, which has caused them to be demolished in order to provide new educational or sports facilities for the neighbourhood population.

It is clear that these transformations challenge not only the Ministry of Health authorities but also architectural conservation professionals and

heritage advocates to find plausible solutions so that this modern heritage can be adapted to new medical theories, thus rethinking heritage from the contemporary city and avoiding irreversible demolition. ■

LELÉ'S ARCHITECTURE OF CARE: THE SARAH KUBITSCHEK HOSPITALS AS A STRATEGY FOR BIRTH CENTRES AND HEALTHCARE SPACES

CARLA ZOLLINGER
LCI BARCELONA

ABSTRACT

The work of the architect João Filgueiras Lima, Lelé, holds an emblematic position in Brazilian architecture. It revisits ethical, formal and constructive themes of the modern architectural movement from previous decades with a high degree of awareness. His work has contributed to the construction of a transforming landscape in cities, designed for the community as an ecosystem connected by uses and bioclimatic adaptation to the surrounding environment. Architect João Filgueiras Lima, better known as Lelé, has explored paths of flexibility and development towards industrialization. Within Lelé's vast oeuvre, his healthcare architecture remains key today to a way of thinking and constructing spaces, inseparable from urban concepts of connection, adaptation, scalability and replicability.

In this sense, this paper proposes a critical discussion of Lelé's works in healthcare, particularly the hospitals of the Sarah Kubitschek Network specialising in musculoskeletal rehabilitation, conceived with the crucial collaboration of the landscape architect Alda Rabello Cunha, the physician Aloísio Campos da Paz and the economist Eduardo Kertész. The aim is to discuss this architecture as a *modus operandis* in the process of city building, based on the premises present in its design, as well as considering its material pre-existence, in constant risk of deconfiguration and disappearance.

The methodological approach is the case study of the Sarah Kubitschek Hospitals, in relation to their conservation, combined with a comparative-propositive analysis of the issue of the architecture of care facilities from a gender perspective in other contexts. We not only examine the architecture of spaces for maternity and birth centres but also those dedicated to providing healthcare for the elderly among others, in order to meet current needs for inclusion and care. The study connects with the research NAIX-EM in which the authors are involved at the Universitat Politècnica de València.

1. INTRODUCTION

This paper[1] proposes a critical discussion on Brazilian architect João Filgueiras Lima, Lelé's works in healthcare, particularly the Sarah Kubitschek hospitals specialising in musculoskeletal health, conceived with the crucial collaboration of the landscape architect Alda Rabello Cunha. The aim is to discuss this architecture as a *modus operandis* in the process of city building, in particular of healthcare facilities.

The methodological approach is the case study of Lelé's hospital designs, with a comparative-propositive analysis of the issue of the architecture of care facilities in other contexts.

The analysis exposes the importance of discussing and comparing these experiences as a methodological discussion. There are several cases of healthcare spaces that can potentially benefit from the strategies developed by Lelé in the Sarah Kubitschek hospitals. Such strategies focus on the component of care and humanization, as well as flexibility and scalability as required by some spaces, which is especially important in the case of spaces dedicated to providing healthcare to the elderly, for example.

This is also the case of maternity spaces, which have inadequately considered from the point of view of women's needs, the flexibility required to attend to the different childbirth processes, and in relation to the diversity of contemporary needs. Its program is particularly suitable for incorporating different uses and relationships in terms of tasks related to caregiving, as well as establishing community relations within the urban fabric, and related to reproductive activities.

In short, the paper investigates the design strategies to guide the conception of spaces in healthcare and birth centres, in particular. At the same time, the reflection serves as an initial step towards further analysis of the state of conservation of Lelé's hospitals: their transformation over time, their restauration, as well as, in some cases, and in an integrated approach, their possibilities for reuse.

Thus, while analysing and incorporating the lessons learned from the works being studied, we also examine the architecture of spaces for maternity and birth centres in order to meet current needs for inclusion and care.[2]

2. CONTEXT

The paper analyses, as a case study for contemporary strategies in healthcare architecture, the hospitals designed by Lelé based on the building-landscape approach and the premise of incorporating the garden into the project. It also incorporates concepts of scalability and replicability through the use of prefabrication. The study focuses on examining the first healthcare buildings conceived by the architect in Brasilia, the capital of Brazil, in the 1960's, as well as the example of the Sarah Kubitschek Hospital in Salvador in the 1990's, which served as the basis for building several other Sarah Kubitschek musculoskeletal health hospitals across Brazil.

To understand these strategies, it is first necessary to provide further context on the first hospital buildings conceived by Lelé, the Taguatinga hospital and the Sarah Kubitschek Hospital in Brasilia's South Wing.

1. Contributors of the paper: Eva Álvarez and Carlos Gómez (Universitat Politècnica de València).

2. The study connects with the research NAIX-EM in which the authors are involved at the Universitat Politècnica de València: "Strategies and models for the improvement of security, functionality and user experience in birth centres" (GVA. INNEST/2023/93) within the European Union's FEDER Programme of Strategic Projects in Cooperation and the Valencian Community 2021-2027.

In 1967, Lelé was invited by Oscar Niemeyer to design one of Brasília's first district hospitals, the Taguatinga hospital, based on the principle of modularity and extensibility, as well as on the flexibility of the spaces so that they could be expanded in the future. Alongside the collaboration of architect and landscape designer Alda Rabello Cunha, Lelé sought to create "terrace-garden areas that function as hospital solariums."[3] The staggered spaces were designed to be occupied initially as roof-top gardens, as an extension of the hospitalisation spaces.[4] The roof-top gardens would serve as a place for patients to sunbathe and get to know the vegetation and natural elements, enhancing care and socialising among the in-patients, linking the indoors and outdoors, and they were considered natural and built for well-being, meetings and care of users.[5] This design strategy is directly connected to seminal references in the period, such as Alvar and Aino Aalto's Hospital for Tuberculosis Patients in Paimio, Finland, or Johannes Duike's Zonnestraal Sanatorium in Holland.

On several occasions, Lelé referred to the influence of Alvar Aalto's work on his projects, especially in regard to the Hospital in Paimio, designed together with Aino Aalto. Visited by Lelé shortly after he designed the Taguatinga project, it was an important source of reference for the conception of the latter. Although very different in terms of programme, it is possible to observe strategies used by the Finnish architects in the basis of the project in Taguatinga, such as that of turning to the landscape through the layout of the buildings and opening them up to the outside. Or the solution of the roof-top terrace for sunbathing and socialising for the patients, conceived by Lelé as a garden terrace, favouring contact with the natural environment as an essential part of the cure.

However, the first hospital conceived by Lelé is also related to other examples in the local context, since, in the 1950s, Brazilian architecture had several examples of hospital architecture based on the exploration of the relationship between the building and the landscape. This premise of incorporating the garden into the building was particularly pursued by the so-called Carioca School, the architects who graduated from the National School of Fine Arts (ENBA), under the direction of Lucio Costa. Among the various projects in this context are those highlighted by Ana Amora, such as the Sanatorium Complex of Curicica, by Sérgio Bernardes, the Lagoa Hospital, by Oscar Niemeyer, the IPPMG, by Jorge Machado Moreira, and the Souza Aguiar Hospital, by Ary Garcia Roza. As the author explains, despite their "different programmes, formal typologies and links with their surrounding area, they are good examples for debating the presence of gardens in the Modern architecture of hospitals in the city of Rio de Janeiro."[6]

These four hospitals, the last three of which had landscape designs by Roberto Burle Marx, laid the foundations for Lelé's experimentation in healthcare architecture with Alda Rabello Cunha, helping to apply the experiences of the so-called Carioca School to the great construction site of Brasília.

Yet the Taguatinga experience paved the way for others. For this same city, Lelé conceived the first hospital for musculoskeletal health in 1980. In the

Sarah Kubitschek Hospital project in Brasilia's South Wing (**Fig. 1**), located on a more compact plot of land, the solution chosen was a vertical display of the programme, in a block of exposed reinforced concrete, considered to be brutalist. Behind the large Vierendeel-type concrete beams on the façades, the hospital housed large gardens for the use of the patients and their carers and relatives. As was the case with the Taguatinga Hospital, in this project the architect Alda Rabello Cunha was involved in designing the architectural solution integrated with the gardens. The gardens designed by the architect were fundamental to the project: "conceived as a mass of vegetation, the gardens integrate logically and functionally with the various types of existing spaces. In the case of the ward terraces, in-patients use these outdoor garden areas as places to socialise and as solariums for daily sunbathing"[7] (**Fig. 2**), so that the gardens and intermediate indoor-outdoor spaces play a central role in the project and in the patients' own healing therapy.[8]

3. ARAH KUBITSCHEK HOSPITAL, SALVADOR

The musculoskeletal health hospital built in Salvador de Bahia, designed by Lelé, inaugurated the expansion of the Sarah network after the construction of the first unit and head office in Brasília, resulting from a partnership contract between the Pioneiras Sociais Foundation and the Brazilian government.

Conceived in 1988, after a period in Rio de Janeiro, this project dates back to the period of Lelé's intense production in Salvador, in the 1980s. At that time, he had carried out an enormous volume of works, produced in the Fábrica da Cidade, FAEC, a factory conceived and built by him for the production of prefabricated parts for the large volume of public works in Salvador, mainly made of reinforced mortar (ferroconcrete). Among others, he designed and directed urban public works and facilities such as schools, kindergartens, university campuses, City Hall, as well as singular works, including collaborating with the architect Lina Bo Bardi.

However, the architect's experience with prefabrication had its origins in his first works in Brasilia, incorporated in the Taguatinga hospital, before the subsequent development in industrial experiences leading to the FAEC. His experience is also related to the context of the architecture of the Carioca School, especially in the field of healthcare architecture, if we look back at previous examples, such as Sergio Bernardes' Curicica hospital in the 1950s, which was also based on the prefabrication of concrete elements.[9]

The Sarah Salvador, from the 1990s, was built on an extensive plot of land, allowing for its horizontal layout, integrating all hospital areas, including those for treatment, hospitalisation, waiting and management areas. It also permitted the inclusion of large gardens connecting, framing or serving as intermediate and natural spaces for collective use on a daily basis (**Fig. 3**). The spaces and areas were designed with facilities and furniture to support daily and community life during treatment. The project was pioneering in the development of bioclimatic air conditioning systems, incorporating natural floor-to-ceiling ventilation made possible as a result of galleries located in the basements to blow air in, and complemented by the sheds located on the roof.

9. Thaysa Malaquias de Mello, "A contribuição do Arquiteto Sérgio Bernardes para a Moderna Arquitetura de Saúde," Master diss. (Universidade Federal do Río de Janeiro, 2018).

One of the premises of the musculoskeletal health hospitals in the Sarah network was to ensure the recovery of the patients and their companions. The hospital has several flats for in-patient care, in addition to the collective facilities, all of which were conceived along with the gardens.

4. SARAH KUBITSCHEK HOSPITALS IN BRAZILIAN CAPITALS

Decades after the first hospital in Brasília, Lelé designed several Sarah Kubitschek musculoskeletal hospital units around the country, including for example a second hospital in Brasília, as an expansion of the Sarah network.

In contrast to the first Sarah, made of concrete, the construction of the new units was based on a construction made entirely of prefabricated elements. Similarly to the Sarah Salvador, which was the first to be built entirely in a prefabricated modular system, the hospital layouts were organised horizontally in single-storey buildings constructed on large plots of land, with the prefabricated parts produced on a centralised scale. The architect built a factory in Salvador to produce the industrialised modular parts, the CTRS, which is a model of industrialisation methodology in hospital construction.

The system was designed to prefabricate all the construction elements of the healthcare buildings, which were configured based on industrially inspired forms, to encourage the use of natural resources in lighting and ventilation, and to create a variety of spaces, including large spans, at a low cost. Serial prefabrication allowed the architect to develop complex designs based on elementary and industrial figures.

The horizontal layout of the programme allowed the different areas of the hospitals to be integrated, from hospitalisation and management to sports and aquatic facilities. The in-patient spaces were connected to gardens and intermediate spaces open to the surrounding landscape. Such spaces were planned for collective use on a day-to-day basis, and designed in accordance with bioclimatic parameters.

The musculoskeletal health hospitals had apartments for patients requiring hospitalisation with a companion, connected to courtyards with gardens.

5. BIRTH SPACES AMONG SPACES OF CARE

Architecture for the process of childbirth has historically been treated within rigid parameters and has been subject to little problematisation as a typology of architecture, given that "the design of hospital spaces for labour and birth has traditionally been developed under surgical parameters and functionality for the professional"[10] and not for the users, in this case, the women who use them. These spaces, constructed within rigid technical-scientific structures, have perpetuated notions and norms without taking into account the diverse experiences and needs of the women for whom they are intended.

The critique of similarly rigid structures is central to the work of Lelé, especially in the design strategies of the natural and built spaces that he developed alongside Alda Rabello Cunha, for the well-being, meeting and care of the people who use them. Lelé's architecture is quite clear in his criticism of the generalized use of air conditioning and artificial lighting

as a rule for all hospital buildings. For him, this unwritten rule created hospital environments that were "much more hermetic and, above all, more unpleasant and inhumane". Contrary to the typical logic of enclosing hospital equipment within a technological bunker, Lelé's projects sought to enhance and favour areas for socialising and public use by connecting interior and exterior, establishing a relationship with the surrounding landscape through the inclusion of gardens in the project.[11]

The spaces related to maternity are often characterised as hermetic and dehumanising, reflecting a strongly hierarchical patriarchal vision. Such a framework sets these spaces in standardized and established areas, preventing proposals outside the medicalized and, in short, controlled areas. Thus, spaces for childbirth have been identified with a surgical unit, leading to a lack of encouragement for other spaces related to maternity. In this context, the World Health Organisation, as early as 2015, warned about the existing problems in health centres, whose physical-spatial configuration, procedures and treatment are linked to situations of violence in the birthing process, recognising the need for research and institutional action, with the crucial challenge of respecting women's health choices.[12] Among these choices are deciding how to give birth, where to give birth, the birthing procedure itself, and the company during childbirth, in a long list. These principles were taken up by the WHO in 2018 and defined in more detail in the form of recommendations to promote "respected labour" or "mobility in labour and position of choice" or "emotional support from a companion of choice", considered as fundamental rights by the World Health Organisation itself.[13] These recommendations, alongside others, were reflected in the WHO Recommendations for care during childbirth, for

a positive birth experience, based on the "importance of woman-centred care to optimize the experience of labour and birth for women and their babies through a holistic approach", considering "the complexity and heterogeneity of prevailing models of care and current practice."[14]

6. LELÉ'S PROJECTS AS STRATEGIES FOR BIRTH CENTRES

Few experiences are supported by deep and wide reflection on different ways of conceiving birth spaces, in Spain, as well as in the Western context. In the current context, health and care have been increasingly treated according to a scientific-productive model, based on hospital care and medicalised treatments.

In such a context, on the one hand it is fundamental to consider how architecture interacts with various disciplines in order to provide insights into the design of birthing spaces, specifically Birth Centres, in relation to different environments and their socio-environmental landscape. On the other hand, it is crucial to explore research on architectural typologies to address strategies and different models for enhancing the safety, functionality and experience of women, their partners and companions in birthing centres.

Thus, the present reflection took the cases of Lelé's hospitals as a basis for research on architectural systems and typologies to address the current and future question of designing and constructing care spaces, in particular Birth Centres, from a conception centred on the users, on the relationship with the natural and built environment, promoting the democratisation of their use, the possibility of flexibility and adaptation to different contexts, as well as production on scale.

In particular, the reflection has aimed to consider spaces that have been analysed very little in terms of their spatiality, such as spaces for maternity. Such spaces have been historically conceptualised, and especially in recent years, based on a highly technical-scientific and medicalised model. Therefore, it has become central to consider the spaces from a woman's perspective, taking into account their specific needs, and the complexity, flexibility and openness that these spaces would require to bring together the different models and processes in a vital and central need, such as childbirth.

The projects of João Filgueiras Lima, Lelé, and, particularly his healthcare architecture in collaboration of Alda Rabello Cunha, constitute an invaluable contribution to modern architecture of the second half of the 20th century in its technical, aesthetic and social possibilities associated with industrialisation and prefabrication, to promote the needs for change in healthcare spaces, especially in maternity care. The study of these works in their architectural typology is therefore an important source for promoting strategies and different models for improving the experience of women and other users in Birth Centres. ■

BIOGRAPHY

Carla Zollinger possesses a PhD in Architecture from Universitat Politècnica de Catalunya, UPC, and holds a M.Arch. in Critic and Project from UPC. She was awarded with the Rome Spanish Academy Grant in Architecture 2024 and she had a Post-doctorate Grant at Universidade Federal da Bahia PNPD-CAPES. She is Head of Research at Escuela Superior de Diseño LCI Barcelona and teacher in the Cities and Urbanism Programme at the Universitat Oberta de Catalunya. She is involved in research on design and urban regeneration and restoration focusing on gender mainstreaming, collaborating with Universitat de Girona and Politècnica de València.

THE INSTITUTO DE PUERICULTURA E PEDIATRIA MARTAGÃO GESTEIRA (IPPMG), BETWEEN GLORY AND RISK

#06

HELIO HERBST
PROARQ/UFRJ,
PPGPACS/UFRRJ

ABSTRACT

In 1949, the formerly named Institute of Childcare and Pediatrics (Instituto de Puericultura e Pediatria - IPP) began to be built in a territory resulting from landfill of nine islands located at Guanabara Bay. The architectural project, designed by a team led by Jorge Machado Moreira, who was also responsible for the urban plan of the University City, was awarded in the category of hospital buildings at the II Biennial de São Paulo, in 1953.

The IPP's physical-functional program, as originally conceived, was distributed into four blocks. The gardens and tile panels designed by Roberto Burle Marx create an active relationship with the surrounding landscape. In 2009, Burle Marx's landscaping and panels were listed by the Rio de Janeiro City Council.

Despite its past glories, including its consecration and the recent recognition of the artistic value of the panels and the landscape design, the complex has suffered damage which has put its physical integrity and visibility at risk.

It is worth highlighting the chronic lack of funding that hinders the carrying out of preventive conservation work and makes the recovery of the gardens and the restoration of the architectural elements of the, at present, Institute of Childcare and Pediatrics Martagão Gesteira (IPPMG, as it is known in Portuguese) unfeasible.

This article intends to examine the current state of the IPPMG, understood in the intricate contrast between the celebration of historiographical narratives and negligent everyday attention. We are also interested in exploring how to create a future that is not necessarily identified with the lethargy that seems to numb different segments of civil society and public power today, endangering the transformations envisioned by its authors.

1. INTRODUCTION

This article discusses the architectural and landscaping concept of the formerly named IPP, an integral part of the University of Brazil, conceived between 1949 and 1953 by Jorge Moreira and Roberto Burle Marx in Rio de Janeiro. The first section, entitled "glory", analyses the design solutions and their integration into the University City, whose urban plan, also signed by Moreira, established guidelines for the development of an area resulting from the association, through landfills, of nine islands in Guanabara Bay. The second section, named "risk", discusses the chronic lack of funds that hinders the preventive conservation and restoration of the currently named IPPMG, despite its importance in terms of heritage. At the same time, it is mandatory to point out the problematic occupation process of the island, observing the diagnoses and guidelines suggested by the last two master plans produced by the Federal University of Rio de Janeiro (UFRJ), created to replace the University of Brazil. Through analysis of these documents, the relationship between the IPPMG, its insertion in the university campus and in the city of Rio de Janeiro is reconsidered.

2. GLORY

The IPP was created in 1937 with the support of President Getúlio Vargas to accompany and provide clinical guidance for children in their physical and mental aspects. In 1945, the IPP separated itself from the Ministry of Education and Public Health, as it became part of the Faculty of Medicine. In the same year, it was decided to establish the University of Brazil on an area of land formed by the landfill of nine islands in Guanabara Bay.

The IPP headquarters began to be developed in 1949, after initial being located in temporary facilities. It was eventually settled with several health facilities in the northern section of the island, adjacent to the road that connects the mainland to Ilha do Governador, where Galeão International Airport is located.

According to Amora e Souza[1], the IPP was perhaps the first building constructed on the campus, made possible through the intermediation of the Presidency. Getúlio Vargas considered it the starting point of a new phase in the history of child support in Brazil.

In the 1952 urban planning version, Moreira envisaged the use of *pilotis* in buildings to guarantee the free movement of pedestrians over large gardens, and the organisation of activities in ten spatially demarcated sectors connected through a monumental road axis that crosses the territory longitudinally.

In relation to IPP's architectural project, Paulo Jardim[2] acknowledges, in addition to the recommendations put forward by Le Corbusier, affinities with the constructive rationality defended by the Bauhaus masters. In this line of thinking, the physical-functional program is distributed in four blocks, with three of them – Ambulatory, Hospital, and Pupillary, which monitors healthy children – implemented parallel to each other and connected transversally by a fourth block, occupied by the Milk Bank.

The implementation of the complex, partially built on *pilotis*, integrates the covered areas with the building's external spaces, especially in areas

for prolonged stays. To achieve this integration effect, Burle Marx defined sinuous contours between the flowerbeds and the pedestrian circulation areas, creating abstract shapes in the floors paving made in Portuguese stone.[3] The association between the patches of vegetation, in the same way, directs the users' gaze towards pre-determined visual axes, creating an active relationship with the surrounding landscape.

In the words of Mário Pedrosa,[4] originally published in 1958:

> *The garden is no longer passive in relation to the spaces and architectural construction plans themselves. Its function is no longer merely to complement the rhythms of structures and open spaces, in the interior-exterior relationship. Instead, it aims to define the spirit of the place. By structuring the surrounding spaces, the artist seeks to create a counter-rhythm that both isolates the architectural unit – allowing it to define and enhance its design and program – and integrates it into a cohesive whole with the environment, climate, atmosphere, light, and nature.*

Materials, colours, and textures accentuate the orthogonality of the façade plans, with a predominance of solid surfaces over voids. Small openings, generally derived from geometric elements, are inscribed in the large masonry panels, and continuous bands of windows are created by the successive alignment of frames.

White ceramic tiles, used in the external masonry, guarantee visual attention, contrasting with the shaded areas of the lower floors and with the artistic panels, whose production refers to two of the aspects of modern tiles in Brazil – patterns and figured compositions –, according to Frederico Morais.[5]

The standardised tiles, signed by Ayrton Sá Rêgo and Yvanildo da Silva Gusmão, were selected through an internal competition among young employees of the Technical Office of the University of Brazil (ETUB in Portuguese). The module proposed by Rêgo covers parts of the outpatient block. It is centred on a meandering blue line that extends diagonally to the adjacent edges. Four small circles, two of which can be found in dark blue, and the other two in yellow, arranged at alternating vertices, serve as complementary connecting elements. The carpet effect, formed by the inverted laying of the pieces, creates a sinuous and continuous weave, with an abstract-geometric character.

The pattern designed by Gusmão wraps parts of the pupillary block. It consists of a diamond-shaped central element, in blue, resembling a weathervane, with the vertices occupied by a quarter of a circle, in yellow. When repeated, this generates a continuous pattern that alters the perception of architectural space.

The figured panel, designed by Roberto Burle Marx, extends into two parts on the southeast facade of the Milk Bank block. The smaller segment, located to the left of the entrance door, serves as the backdrop for a small garden. The other part of the panel, on the right, is also installed on a recessed wall, originally illuminated through a cut-out in the covering slab. The tiles are polychrome in shades of blue and yellow, arranged in layers of

different thicknesses, that interpenetrate or overlap with linear interferences in a composition alluding to cubist aesthetics.

The plot proposed by Rêgo tends towards the informal, while that by Gusmão creates a visual vibration, close to that of kinetic art. In Morais's assessment, both work to "relieve the building of its constructive rigidity; They are like a visual rest area."[6]

The Burle Marx panel, in turn, combines the tile technique with easel painting, serving as a sealing element and a coloured background to enhance the plants. Furthermore, it fosters the interaction between public and private, with art humanising the landscape.

The IPP project was awarded in the hospital buildings category at the II São Paulo Biennial (1953).[7] Two years later, the building was part of the Latin American Architecture since 1945 exhibition organised by the Museum of Modern Art (MoMA).

Regarding the IPP, the New York exhibition catalogue points out the refinement of the architectural solutions in the scale of detail, and the careful execution of the building, rarely observed in Rio. Furthermore, it highlights the presence of elements that characterise modern Brazilian architecture, such as "Burle Marx tiles, openings made of ceramic elements and vaulted roofs, treated with the greatest moderation."[8]

Henrique Mindlin (1956) analyses the University City on his *Modern Architecture in Brazil*, which was considered the largest campus in the country at that time. It cites the IPP and, through photographic reproductions, values the monumentality of the Clinical Hospital building and the geometric accent of the National Faculty of Architecture (FNA in Portuguese). Mindlin also emphasises the sobriety of the IPP's architectural project, whose regional character is accentuated by the contrast between the blocks and their smooth surfaces covered with panels designed by Gusmão, Rego and Burle Marx.[9]

Despite appearing in the main specialised periodicals and in practically all critical inventories of Brazilian modern architecture, the, at present, named IPPMG is only listed provisionally because of Burle Marx's gardens and panels, through a municipal decree established in 2004, to safeguard a set of 84 works, in consideration of their importance for the configuration of Rio's cultural landscape.

3. RISK

As it is impossible to provide a detailed discussion on the process of occupation of the university campus or pinpoint causes and responsibilities for the decisions behind the insufficient funds to build and maintain its academic units, it is worth mentioning some facts that contributed to its degradation.

The transfer of the federal capital to Brasília not only symbolically repositioned the city of Rio de Janeiro in the country but also impacted the distribution of financial resources. Similarly, the reframing of the University of Brazil as UFRJ, part of the federal higher education network, can be considered an authoritarian paradigm of the civil-military dictatorship that governed the country between 1964 and 1985, according to Queiroz.[10] The

university reform, inspired by the US organisational model, contributed to further isolating the already spatially fragmented academic units.

The construction of teaching and research centres on campus was prolonged for decades, in a process marked by a lack of resources and by the refusal of some academic units which opted to remain in central areas. As a result, some of the empty spaces created were occupied by various federal agencies.

In the 1990s, the IPPMG surroundings were severely altered with the construction of a highway that encroached upon, practically suppressing the frontal setback of the Ambulatory block, leading to the destruction of flowerbeds and contributing to deteriorate the atmospheric and noise conditions. Similar losses occurred with the establishment of two bus terminals just in front of the plot.

According to a survey carried out in 1999, which was later included in the last two UFRJ master plans concluded in 2011 and in 2022, the conservation of the IPPMG received a regular rating, and facilities were in full operation at the time. The external coverings were worn and partially detached. Possibly due to poor maintenance of the roof's waterproofing, leaks were observed at several points. In addition, fences were installed on the *pilotis* of the ambulatory block to prevent the occupation of the homeless.

In the aforementioned survey, the kindergarten (Escola de Educação Infantil—EEI in Portuguese), which occupied the premises of the former daycare centre, was equipped with eight classrooms, a reading room, and a toy library. On the ground floor, the *pilotis* were still covered in Portuguese stone, although some had deteriorated. It was identified that several cobogós (ceramic hollow wall elements) were loose, putting users at risk.

It cannot currently be stated that the IPPMG conservation remains regular. In fact, by any asset evaluation criteria, it would receive the worst possible evaluation. Nor can it be said that the building complex remains in full operation: the EEI has been closed since February 2023, as determined by a technical report, which pointed out structural issues in the Pupillary block.

Can we envision some type of reversal to the imminent collapse of the IPPMG? What does the future of the University City deserve?

According to the UFRJ-2020 master plan, drawn up during the economic boom that characterised the decade that preceded the World Cup (2014) and Olympic Games (2016), it was believed this would be the urban requalification of the campus and the full recovery of its built heritage.

The main goal of the PD UFRJ-2020 was the principle of double integration, between the units that make up the campus and its connection with the city of Rio de Janeiro. Aiming to reverse the fragmentation that constitutes the root of a project "whose conception, politically authoritarian and urbanistically faithful to the canons of an uncritical modernism,"[11] it was proposed to introduce shared-use equipment. This change aims to unite the academic community, radically transforming the current standard, which prioritises individual transport, isolation between units, low density and separation of uses.

In design terms, this optimism was translated into a broad urban reformulation, structured into six Convergence Centres, distributed

Figure 3. Map of types of UTGs in the University City, adapted by the author. © Helio Herbst, 2024, after UFRJ, *Caderno de Diretrizes. UFRJ Plano Diretor 2030* (Rio de Janeiro: UFRJ, 2022), 42.

throughout the island. These hubs would bring together classrooms and shared equipment – auditoriums, restaurants, residences, libraries, commercial establishments –, unified through an innovative internal transport system, whose magnetic levitation trains are powered by electrical energy.

The plan also predicted the construction of a branch of the metropolitan railway company and the implementation of waterway transport to the city centre, diversifying access options.

Almost nothing came to fruition.

At the end of the PD UFRJ-2020 term, a new commission was appointed to prepare the 2030 master plan. In general terms, the plan advocates a non-expansionist approach, focusing on the recovery, optimisation, maintenance and sharing of open spaces and buildings.

The PD 2030 recognises the University as its greatest asset. Under this reasoning, it proposes measures for the recognition, appreciation and dissemination of places, spaces, and activities that participate in the cultural identity of UFRJ. According to the document:[12]

> *The proposal of an integrated conservation plan of the university heritage is a most relevant attitude towards the technical, social, and cultural sustainability of our built and environmental cultural patrimony. Museum spaces, places of memory, and spaces of sociability are important components of the institution's cultural identity.*

Based on the blocks' characteristics of use and occupation, limits were created for the management of spaces and facilities for collective use. This delimitation resulted in the so-called Territorial Management Units (UTG in Portuguese),

12. Universidade Federal do Rio de Janeiro, *Caderno de Diretrizes. UFRJ Plano Diretor 2030* (Rio de Janeiro: UFRJ, 2022), 20.

which contain the buildings and their surroundings, as well as circulation routes, preservation areas and buffer strips around the buildings of each UTG.

Among the nine types of sub-units, we are interested in examining UTG1, which includes the listed modernist buildings. The IPPMG and the Faculty of Architecture and Urbanism (FAU) are found in this category. In accordance with standards recommended by international organisations, UTG1 foresees the establishment of an envelope with the aim of protecting the neighbourhood of the listed property, prohibiting construction that impedes its visibility and that alters the ambience and historicity of its context.

The confrontation between the last two master plans indicates the setting for discussing Brazilian politics. In PD UFRJ-2020, the optimism generated by the economic boom led by the left in the federal government motivated the proposal of an ambitious plan for the densification and diversification of activities on the campus. Those proposals were linked to new modes of transport, aiming to integrate the island with the city centre.

PD 2030, however, takes into account the budget constraints imposed by the extreme right, in power between 2019 and 2022. Such adversities resulted in actions more focused on the management of built heritage, with conservation parameters defined by each UTG.

Unfortunately, despite stopping attacks against democracy and science, the left's return to the federal government has not, to date, had the desired impact on the conservation of the campus. Its listed buildings continue to degrade on a daily basis, contradicting the belief in the capacity of modern architecture, in communion with the arts, to transform society through a new plastic order for the well-being of the entire community.

In an attempt to reiterate the importance of safeguarding the IPPMG and upholding the achievements and promises of transformation embodied in its architectural and landscape project, it seemed pertinent to refer to an excerpt written by César Floriano, in which the work of Burle Marx is recognised as "the blunt expression of an artist committed to and believer in the modern project". Furthermore, in the author's words:[13]

> *We have to look at Brazilian modernity from a broader reality. A modernity that used the resource of creative freedom not as a misleading ideology or as a replacement for an absence of transformations in the social base, nor as a rhetorical formula. Brazilian modern art was fully committed to the country's social, technological, and cultural reforms. An aesthetic statement driven by a desire to connect art and existence, assuming experimentalism as a necessary condition to create an artistic status.* ■

CIRCULAR ECONOMY AND BUILT HERITAGE: OBSOLESCENCE, CIRCULARITY, INSTRUMENTS AND FUTURE

RENATO D'ALENÇON CASTRILLÓN
PONTIFICIA UNIVERSIDAD CATÓLICA DE CHILE

DOMINGA TEILLERY DELATTRE
PONTIFICIA UNIVERSIDAD CATÓLICA DE CHILE

ABSTRACT

Building construction contributes 35% of the total waste worldwide annually, and it has the greatest potential to influence a reduction in GHG emissions driving climate change. In this context, heritage conservation and the reversal of built stock obsolescence, be it material, functional, or cultural have become problems and potential strategies for sustainable development. Various authors propose Circular Economy (CE) strategies that seek to extend the useful life of buildings, but: what is the scope of these strategies faced with specific heritage values?

In this article, we discuss and contextualise the concepts of Circular Economy as applied to the built environment and particularly to built heritage to set a context and precisions on several relevant concepts and to enhance the broader discussion.

1. INTRODUCTION

Building construction generates 35% of the total waste worldwide annually, and it has the greatest potential to influence a reduction in GHG emissions driving climate change.[1] The construction industry is thus widely considered a key sector for an effective transition to sustainable development and a circular economy. The linear economy paradigm: "Extraction-Manufacturing-Use-Disposal" must be re-defined towards a production model that guarantees the use of resources at their maximum potential for as long as possible.

The implementation of a new production model based on a Circular Economy (CE), "a system where materials never become waste and nature is regenerated,"[2] is currently proposed as one of the most necessary and effective solutions to combat this problem: the Circularity Gap Report 2021, an annual report that measures the state of circularity at a global level, shows that the world economy is 8.6% circular, making it necessary to achieve at least 17% circularity to live in a prosperous and habitable world. Given its impacts, the construction industry is usually considered a key sector for an effective transition to CE. Within the six industries with the highest environmental impacts, the construction industry has the greatest potential to influence the temperature decrease that impacts climate change.[3]

2. OBSOLESCENCE, HERITAGE AND SUSTAINABILITY

In this context, the construction industry needs to find alternatives to the simple demolition of obsolete built stock, which turns buildings into waste (Construction and Demolition Waste, CDW). Thus, its obsolescence is increasingly widening its traditional scope and becoming a sustainability problem. If the linear structure is characteristic of the conventional production system - from extraction, construction, operation, to disposal - the material conditions, use, and cultural relevance of buildings can also be considered in this process. Such articulation poses a conceptual, economic, and cultural challenge, that must also be placed in the perspective of its environmental impact in a comprehensive manner.

The architectural tradition towards the existing stock has been focused on the cultural value of a built heritage embodying the broader social, historical and technological understanding of the societies that built them. Perhaps influenced by the methods of archaeology, which transformed ruined remnants into material repositories of history to be decoded in spatial, economic, or social terms,[4] or by the representative load of the continuity of social and political institutions such as the church or the state, built heritage gained, in the last 50 years, a status beyond its direct meaning as an asset, to be enshrined as an object of devotion.

Daniel Abramson emphasises the concept of obsolescence as we understand it, being relatively new, triggered by the powerful drive towards urban densification of the 20th century.[5] It was not the derelict infrastructure, succumbing to its weight or being destroyed by a natural catastrophe such as an earthquake that ended the useful life of a building. Instead, it was elements such as sudden changes in use or land price that rendered buildings unfit and led to their demolition, even if they had been built relatively recently or if they were structurally sound.

3. Matthew Fraser, et al., *The Circularity Gap Report*, 2024

4. David Clarke, *Spatial Archaeology*. (London; New York: Academic Press, 1977)

5. Daniel Abramson, *Obsolescence*.

Following Abramson's argument, we could say that obsolescence, beyond the debate between destruction and conservation and albeit broadly understood, is a problem of modern cities and modern architecture.

On the other hand, Calduch proposed the decline of modernist architecture as shown in three ways: 1) physical deterioration; 2) obsolescence of use (the constructions no longer served the purpose they were designed for; and 3) the loss of its cultural and social meaning.[6] These categories act as a starting point to detect obsolescence. After this diagnosis, the problem can be abstracted for future solutions, enhancing the building's attributes. Strategies based on these assessments can then be implemented to extend their useful life. However, what exactly are these strategies? There is no established formula to equally extend the useful life of all buildings; each case requires a specific analysis to diagnose problems and propose solutions.

3. CIRCULAR ECONOMY AND BUILT HERITAGE

Circular Economy has gained wide support as a solution to this problem, aiming for the circularity of the construction, use, and demolition processes of buildings, and thereby prolonging their useful life by taking advantage of the existing structure and restoring the initial function of serving the community again. This trend calls for a radical shift in production and consumption patterns, supported by a raft of new government policies.

Various authors[7] propose circular economy strategies that seek to extend the useful life of buildings. At the same time, applying CE principles to buildings requires overcoming a series of technical, logistic, and cultural challenges, among which the definition of metrics and indicators stands out to evaluate and certify that buildings exhibit these circular attributes.[8]

The concepts of CE applied to the preservation of modern architectural heritage and its projection over time will be the conceptual framework for investigating the architectural potential and discussing proposed projects and tools that problematise various CE strategies applied to modern heritage conservation at various scales.

Specific strategies have been stated and developed nationally and internationally to integrate CE in the construction sector. In academic literature,[9] various strategies necessary for the incorporation of these principles have already been proposed: the careful consideration of the life cycle of the work, the integration of circularity criteria in the design stage ("upstream"): Urban Metabolism, flows and banks of materials; Design for Disassembly (DfD); layered design (layers – 7s); programmatic and structural flexibility; open structures and supports; adaptive reuse; maintenance and repair; urban mining; heritage conservation; improvement and maintenance. In the same way, several official international organisations have raised this need, such as the Circular Economy Action Plan (CEAP) of the European Commission.[10]

All these allow us to understand buildings built from a circular perspective as processes rather than products.

4. CIRCULAR ECONOMY METHODS

Despite the fact that there are various systems for assessing the environmental impact of products, including construction materials, the structured implementation of CE criteria in buildings has yet to be developed. A variety of methodologies and evaluation criteria were collected[11] when categorising CE concepts applied to the construction industry and reviewing evaluation methods used for CE in this context. Key areas highlighted include waste management, environmental impact reduction, and the design of products, materials, and buildings. From this review, we have built a discussion with two main elements: 1) Metrics for EC in Construction; and 2) Life Cycle Assessment (LCA) as an analysis platform for EC.

4.1 METRICS FOR EC IN CONSTRUCTION

In the shift towards CE, quantifying the circularity of products and services is crucial to designing business policies and strategies, and prioritising evidence-based sustainable solutions.[12] The same authors conclude that "none of the existing metrics is addressing the concept of CE in its entirety". The European Commission has implemented LEVEL's,[13] a European framework for sustainable buildings, which uses basic sustainability indicators to measure the impacts of carbon, materials, water, health, comfort, and climate change throughout the life cycle of a building. Other initiatives are WBCSD's Circular Transition Indicators (CTI),[14] a tool and framework used to measure circularity for different industries and localities, and Circulytics - Circular Building Toolkit,[15] a platform for integrating circular design strategies that are framed in European regulations and certifications.

4.2 CE AND LCA IN THE BUILT ENVIRONMENT AND BUILDINGS

Several authors[16] highlight that one of the most widespread and used EC evaluation methods in the construction industry has been that of Life Cycle Assessment (LCA). Other authors[17] have pointed out that as a result of the variety of studies existing to date, the LCA methodology presents multiple limitations for the evaluation of buildings. These include considerations of the building's context, the complexity of the design model behind it, a scenario of uncertainty about future changes that affect it, impacts on human health and well-being, data on recycled material, and a lack of consideration of social and economic aspects. Some of these observations have already been raised, pointing out that the construction industry is responsible for inefficient resource management due to characteristics specific to each local industry, such as the lack of integration, lack of cooperation, and waste of resources.[18]

The LCA methods applicable to CE face significant gaps that hinder their application in developing specific solutions tailored to the area.[19] Within these, problems associated precisely with their lack of capabilities and conditions to integrate into building design processes and their subsequent administration stand out, given that LCA is not directly articulated with information modelling systems, such as Building Information Modelling (BIM), nor does it include methodologies specifically developed for the construction industry, which in

turn limits its ability to support decision making in the design stage. In addition, the lack of information and integration capabilities for temporal variables neglects the support that the system could provide during the life stages of the building after its design: construction, use, maintenance, and demolition.

5. CIRCULAR ECONOMY AND MODERN HERITAGE

Very few scholars have specifically discussed the articulation between Circular Economy and Built Heritage. Huuka and Vestergaard articulate them on a conceptual level, proposing that CE and Heritage Conservation aim to preserve "value," which they define differently; they favour a minimum material intervention, on different grounds.[20] Furthermore, they argue building conservation could benefit from adopting the vocabulary and methods of CE, such as Life Cycle Assessment[21] or Material Flow Analysis.[22]

This integration stems from an original contradiction, as CE is born of industrial ecology and thus focuses on reductive cycles and their material re-circulation, while architectural conservation is, in origin, conservative of an original status and meaning, thus "sceptical towards buildings being re-contextualised, re-interpreted." Reciprocally, when it comes to the built environment in particular, CE can find much to learn from building heritage conservation.

Such opposition is suggestive and raises a challenge for mutual learning from these disciplines, for the integration in professional building practice and further research and scholarship.

6. ADAPTIVE REUSE, A PRECURSOR

Adaptive Reuse is an already consolidated strategy to preserve the cultural heritage of significant buildings, through critical rehabilitation and restoration strategies. The objective is to maintain the building's historical and cultural character, adapting it to the new needs of its users while preserving its value, an objective matching those of CE.

Through studying obsolescence, we can thus distinguish between material, functional, or cultural obsolescence[23] to understand the aspects in which the building is not fulfilling its initial function. On the contrary, there is a general purpose, which is to return the usefulness of the buildings to the community without the need for rehabilitation that imitates the original function but rather adapts to current needs.

Francesca Lanz and John Pendlebury outline an overview of Adaptive Reuse approaches, characterising it as an "autonomous discipline" stemming from the reaction to radical urban planning in the 20th century. It emerged in the 1970s and finds today its own conceptual frameworks and disciplinary contributions beyond the disciplines of architecture and design.[24] They claim that since the 2000s, Adaptive Reuse has gained momentum and become a mainstream topic in scholarly circles, if not in professional ones, reflecting a cultural attitude of our time, stemming from the slogan "Reduce – Reuse – Recycle" – a clear antecedent of the circular economy in the 2010s, also appropriated by architectural discourse - if not practiced - in those years, as shown in the German Pavilion at the Venice Biennale 2012[25] or the Australian Pavilion in 2018.[26]

20. Satu Huuhka and Inge Vestergaard, *Building conservation and the circular economy*

21. LCA is defined by ISO 14040 as the compilation and evaluation of the inputs, outputs, and potential environmental impacts of a product system throughout its life cycle. https://eplca.jrc.ec.europa.eu/lifecycleassessment.html

22. Material flow analysis (MFA) is an analytical method to quantify flows and stocks of materials or substances in a well-defined system. Brunner, P.H.; Rechberger, H. (2004). Practical Handbook of Material Flow Analysis. Lewis Publishers, New York.

26. Mauro Baracco and Louise Wright, *Repair: Australian Pavilion, 16th International Architecture Exhibition, La Biennale Di Venezia 2018*. (New York, New York: Actar, 2018)

Interestingly, regarding the concept of RRRs, Ana Tostões suggests integrating this Circular Economy sphere with Modern Movement architecture for the first time.[27] We should consider this a precursor in problematising such integration, although not yet in an explicit tone with Circular Economy, but with its conceptual antecedents RRR. Tostões claims: "I consider that the reuse project is starting to "make history" and I share the idea that heritage transforms itself with us". Through Adaptive Reuse, it is possible to preserve the cultural heritage of significant buildings, through rehabilitation and restoration strategies. The objective is to maintain the historical and cultural character of the building, adapting it to the new needs of its users.

The way to integrate Circular Economy and Modern Heritage is therefore open to further exploration of a series of relevant and critical topics, which are in different degrees of consolidation and development, such as Obsolescence, Rehabilitation, RRR, Adaptive Reuse, Curated Decay, among others. These suggest a variety of substantial discussions are still to be sustained and developed.

7. CONCLUSION

In the last decade, the Circular Economy has emerged as the new approach to achieving sustainable economic development in the building sector. The concepts of Circular Economy applied to the preservation of modern architectural heritage and its projection over time will be the conceptual framework to investigate the architectural potential and discuss proposed projects and tools that problematise various CE strategies applied to (modern) heritage conservation at various scales.

The Circular Economy and Life Cycle Assessment tools are suggested for use in investigating architectural potential and preparing a project proposal, defining strategies, evaluating performance, and preparing the design.

The way to integrate Circular Economy and Modern Heritage is therefore open to further exploration, of a series of relevant and critical topics, which are in different degrees of consolidation and development, such as Obsolescence, Rehabilitation, RRR, Adaptive Reuse, Curated Decay, among others. These suggest a variety of substantial discussions are still to be sustained and developed.

The session introduced by this paper invites contributions to discuss such problems integration as a process; to study the impact of the passage of time on buildings, both in material wear and the change in requirements and uses; and to consider their re-design potential, considering the reduction of resource consumption and waste generation in the construction, occupation, and demolition stages. ■

STUBBORN ARCHITECTURE: PREINDUSTRIAL PRINCIPLES OF SLOWING BUILDING MATERIAL USE IN THE USE-STAGE

#07

TOBIAS HENTZER DAUSGAARD
AARHUS SCHOOL OF ARCHITECTURE
RØNNOW LETH & GORI A/S

ABSTRACT

Material use in the use-stage of buildings today is overlooked, yet significant. This paper explores what design principles enabled a preindustrial 200+year-old building to have lower material resource use – '*metabolism*' – in its use-stage than an industrialised building of Late Danish Modernism. This is to inform contemporary, industrialised building practice to lower material resource consumption and waste generation in a 200-years timeframe. The average lifespan of buildings in Denmark is 200 years. Yet, continuous renovations, transformations, and replacements of building components drive a use of building materials whose environmental impact is largely unaccounted for in Danish building code. This is despite that the renovation industry is about double the size of the new-build industry, and that 65% of environmental impacts from renovations stem from the use of materials. The shift from vernacular to industrialised building practices took off during Danish Modernism (1933-1974) and introduced new material cultures, construction practices, and design thinking that contemporary building culture is reminiscent of. Based on the previous quantitative findings that the metabolisms (in kg CO2-eq./m2/year) of the preindustrial case, Søkvæsthuset (*1755), was 11 times lower than the industrialised case, Tingbjerg Dormitory (*1972), the paper uses a qualitative comparative case study to analyse what design principles led to this difference in metabolisms. The analysis uses the four lifespan-lenses in BUILD/Aalborg University's theoretical lifespan-framework and takes the façade walls of the two cases as the primary object of comparison. Six design principles of low-metabolism were identified in this comparative analysis: *'robustness hierarchy', 'incremental care', 'legibility', 'multiple purposes', 'singularity'*, and *'clear boundary'*. These principles may contribute towards the design of stubborn new-builds and careful adaptive reuses of existing buildings, such as from the Modern period, to resist the pressures of time with a minimum of resource use in a 200+years perspective.

ACKNOWLEDGEMENTS:
The paper as part of an industrial Ph.D.-project funded by Innovation Fund Denmark (≈50%) and Rønnow Leth & Gori A/S (≈50%), hosted at Aarhus School of Architecture with supervising Professors Mogens A. Morgen, Marie Frier Hvejsel, and Lotte M. Bjerregaard Jensen who thus contributed to this paper.

1. INTRODUCTION

The paper investigates design principles of low material resource use in the use-stage of two cases, one preindustrial building and one building of Late Danish Modernism, to inform contemporary building practices.

Buildings' material change and environmental impact from material use in their use-stage are currently overlooked in Danish building code[1]. While buildings are predicted to last 200 years on average in Denmark[2], parts are often being replaced or altered more rapidly. The significance of resource flows generated in buildings' use-stage is indicated by the Danish renovation sector's production value that is about 65% bigger than the new constructions industry[3], and by the large share (60-65%) of renovations' environmental impact coming from the production of building materials[4]. This resource use is unsustainable from both whole-life-costs and climate perspectives[5], and has been criticised for compromising preservation values, not least in Modern Heritage buildings[6], diminishing lasting architectural qualities.

The paper builds on the quantitative findings in *Hentzer Dausgaard et al. forthcoming* of resource flows and lifespans of components mapped and compared across three cases: one preindustrial case, *Søkvæsthuset* (*1755, **Fig.1**) compared to the industrialised *Tingbjerg Dormitory* (*1972, **Fig.2**), constructed after the *Montage Circular* (1960) subsidised industrialised housing constructions in Denmark[7]. Thus, Tingbjerg Dormitory was chosen to represent the industrialised building culture that persists today. To overcome the difficulty of comparing two primary cases of different locations, weathering conditions, design quality levels, maintenance/repair cycles, and programmes, a third case, the mostly preindustrial *Tingbjerg Family Housing* (*1958, **Fig. 2**), was added as control case, facing the Dormitory in the same street, by the same architect and housing administrator, and with a comparable programme.

The concept of "metabolism"[8] was used as a unit to account for material use in the use-stage of buildings, measured in kg CO2-eq./m^2/year of LCA A1-A3 modules. Despite Søkvæsthuset's many whole-building adaptive reuses – from orphanage, to hospital, barracks/prison/court, academy, offices, and library/association facilities – its metabolism was 11 times lower (0,43 kg) than Tingbjerg Dormitory's (4,83 kg) and 20% lower than Tingbjerg Family Housing (0,54 kg). The small metabolic difference between Søkvæsthuset and the control-case relative to the Dormitory means that the differences in location etc. were marginal contributors to the metabolism results. Further, the heritage-listing of Søkvæsthuset in 1918 only decreased its metabolism by 13% in the following 100 years, which therefore does not challenge the overall results either. The found metabolic shift from preindustrial to industrialised building cultures during Danish Modernism (1930-1974[9]) suggests that design principles of low-metabolism could inform new-builds and adaptive reuse building practices today.

2. RESEARCH QUESTION

What design principles contributed to a low-metabolism in the comparison of façade walls between preindustrial and industrial buildings, and how may they inform the design of low-metabolism architecture today?

3. METHODS AND CASE SELECTION

The previous quantitative findings enable a direct qualitative comparison between the lifespan qualities that led Søkvæsthuset and Tingbjerg Dormitory to have different metabolisms[10]. The paper uses a "comparative case study analysis"[11] of cases chosen with *Flyvbjerg 2006*'s strategies to select few cases of rich information contents[12]. The preindustrial case is chosen from before 1824 (200+years-old), and the industrialised case and control case are chosen from the period of Danish Modernism (1930-1974) on either side of 1960. With the earliest case being from 1755 and the latest from 1972, this is the period of study. Søkvæsthuset is analysed with the descriptive theoretical framework by BUILD, Aalborg University, that divides building lifespans into four 'sub-lifespans': "Technical lifespan" where a component is technically/physically able to perform its original function, "Functional lifespan" where the need for a component's original function persists, "Economic lifespan" where maintaining/repairing a component is viable, and "Aesthetic lifespan" were the "aesthetic standard" of a component is maintained in the eyes of the users[13]. Based on differences in lifespans and metabolisms, Søkvæsthuset is analysed and dialectically compared to Tingbjerg Dormitory within these four categories, to form hypotheses of design principles of low-metabolism. Due to page limits, the study focuses on façade walls since the building envelope accounts for most of Danish renovation activities[14].

4. RESULTS

Six design principles were identified from the comparison of Søkvæsthuset's and Tingbjerg Dormitory's façades through the BUILD-framework: *robustness hierarchy*: increasing technical and aesthetic robustness where most wear is expected, *incremental care*: components should be maintainable/repairable rather than needing full replacements, *legibility*: a component's purposes and upkeep should be self-explanatory across generations of users, *multiple purposes*: a component should have qualities within multiple types of lifespan-parameters, *singularity*: a component should be irreducible rather than a composite of sub-elements, and *clear boundary*: an authoritative envelope resistant to changes and expansions.

5. ANALYSIS

5.1 THE CASES

All three cases are located in the Municipality of Copenhagen. Søkvæsthuset was built as a public orphanage and workshop in a then-poor neighbourhood within the city walls, realised by the esteemed bricklayer/builder J.C.Conradi for the Danish King. The two Tingbjerg-cases were realised as part of a big garden city-inspired social housing-only masterplan at the edge of the municipality, facing the green area of Utterslev Bog/lake. Designed by two of the foremost architects of the Danish Modern Movement, professor, author, urban planner, and architect Steen Eiler Rasmussen, and professor and renowned landscape architect, C.Th.Sørensen, the interplay between the large, green open courtyards and the mostly-low housing blocks emerged

as a key motive[15]. In the following analysis, the building envelopes of Søkvæsthuset and Tingbjerg Dormitory are compared.

5.2 TECHNICAL LIFESPAN

The overall robustness of Søkvæsthuset's plastered solid brick façade wall made it survive severe negligence of maintenance[16]. Its particularly robust granite base and visually less vulnerable, dark, brown-plastered plinth at the street level have likely slowed the maintenance cycle where most wear and tear would be expected – akin to the tall concrete base of Tingbjerg Dormitory.

As of 1960, housing – Tingbjerg Dormitory included – was state-subsidised with a requirement to be "untraditional"[17], without the advantage of time to learn from past mistakes, and thus born with prototypical errors that have paved the way for the improved industrialised practices of today. The technical robustness of the Dormitory's façade owe to this fact, but differs more fundamentally from Søkvæsthuset's at two levels: by its making and legibility over time. The Dormitory's hard-surfaced, industrially fabricated-and-perfected components do not lend themselves to be gradually maintained/repaired by hand or otherwise: elements are worn until they are technically obsolete and need replacement or even full-scale renovation. Tingbjerg Dormitory is advertised to prospective tenants as "comprehensively refurbished", "new-refurbished", and "modernised"[18]. In this context, *newness* is used as a quality metric, in which *ageing* would imply loss of performance and value. For Søkvæsthuset, this is different: The softer plaster can be continuously maintained and incrementally repaired by skilled hands, and if anything, ageing signifies that generations of owners have found it valuable enough to continuously care for.

The traditional wall build-up of Søkvæsthuset's façade wall made maintenance and repair cycles more legible to craftsmen and users over time. On the contrary, to comprehend the purposes, qualities, and possibilities of upkeep of Tingbjerg Dormitory's different and materially complex wall build-ups, one needs access to descriptions/drawings and more specialised knowledge.

5.3 ECONOMIC LIFESPAN

The up-front investment of constructing the originally state-owned building with a thick, robustly built façade took a long-term view on state-spending. Tingbjerg Dormitory was realised with a different vision: how to deliver as many inexpensive homes of a decent quality in the shortest amount of time as possible. In a 270-years whole-life-costs perspective, Søkvæsthuset's incrementally maintainable façade is likely economically advantageous compared to Tingbjerg Dormitory's full-scale renovations/replacements every 20 years. Over shorter time-intervals with no renovations needed, say 15 years, the operation costs of the Dormitory would likely outperform Søkvæsthuset, especially since Søkvæsthuset was built at a time of low labour costs and high material costs, contrary to today[19].

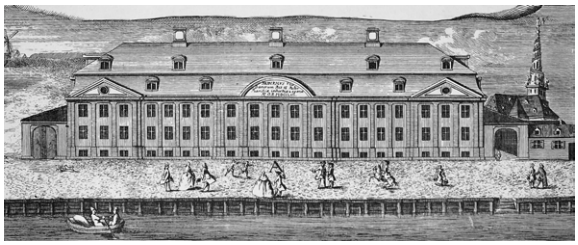
#07

5.4 AESTHETIC LIFESPAN

The stringent, symmetrical architectural order of Søkvæsthuset's façade remained unaltered since 1755, and its heritage-listing in 1918 attests to its architectural/aesthetic and cultural/historic value[20]. The façade wall gains sculptural depth with the rhythm of lesenes framing setbacks around windows, which differentiates the wall into many thicknesses, ranging from 74-98 cm. Increased thicknesses with lesenes enable more structural loads to be carried in the areas that are not punctuated by windows and doors[21]. This dependency of the structural logic on the architectural order is hardly a surprising design insight to architects. Nonetheless, when elements had more purposes – across lifespan parameters – they were found to last longer in the two cases. The Dormitory's window/parapet-elements are examples of visually and materially recognisable non-structural elements, which were fully replaced twice. Tingbjerg Dormitory's non-structural sandwich-elements of the façade have benefitted from appearing as if they were structural and expressed an architectural order – as walls towards the street and column-like wall pieces towards the garden. They avoided replacement, but were, however, partially reclad. Søkvæsthuset's façade frontons are examples of the absence of more lifespan purposes: their narrow aesthetic purpose as adornments resulted in demolition of the rear-frontons and redecoration of the central one, responding to fluctuating aesthetic preferences and functional needs.

5.5 FUNCTIONAL LIFESPAN



Søkvæsthuset's massive façade walls can, like ancient vernacular walls, "store and radiate" heat in cold temperatures, and even out temperature differences over the cause of the day (cooling at day, heating at night) in warmer temperatures[22]. This thermal quality is inseparable from its technical, aesthetic, and economic purposes/qualities, all properties of its singular form. The Dormitory's façade walls have a more complex wall build-up, and is composed of four parts: sandwich-elements, window/parapet-elements, curtain-wall-glass-facades, and exposed, fibre-cement cladded decks. For example, the parapet originally consisted of five layers, each performing a specific task, yet mainly within functional/technical lifespan dimensions: fibre cement-cladding (waterproofing), wind film and vapour barriers (wind- and watertightness), insulation (thermal capacity), and wood cement boards (stiffness). The separation of purposes into physically separate layers conceptually abstracts the qualities of the parapet into different performance goals where each layer becomes vulnerable to the pressures of modernisation/optimisation – such as increasingly restrictive building codes and technologically advancing insulation materials quickly rendering the window/parapet-elements' performance obsolete, resulting in several replacements.

Another difference between the cases is the 'authority' of their respective boundaries. The Dormitory's non-structural façade, with perpendicular structural walls hidden behind it, enabled outwards expansion. The curtain-wall glass-facades and protruding balconies of the common kitchens formed the formally and structurally least clear boundary which was radically altered

several times. By structural and formal layout, Tingbjerg Dormitory allowed for change – both for operational energy upgrades and expansions of common kitchens. The nearly 1 meter massive façade wall of Søkvæsthuset did not change, apart from the occasional blocking and unblocking of windows in the gable facades, and thus formed a clear and authoritative boundary hesitant to change, even through rising comfort levels and energy efficiency standards. The flexibility and adaptability inherent to the plan layout of the Dormitory clearly delivers value to its users by offering opportunities to expand or alter the spaces over time, yet, from a low-metabolism perspective, the '*stubbornness*' of Søkvæsthuset's wall makes it superior.

5.6 DESIGN PRINCIPLES

ROBUSTNESS HIERARCHY

As seen in the dark-coloured mineral base/plinth of Søkvæsthuset and Tingbjerg Dormitory, technical and aesthetic robustness of the façades were increased in the areas where most wear and tear were expected, which resulted in slower maintenance/renovation cycles.

INCREMENTAL CARE

Differences in construction techniques and in components' maintainability influenced the overall material use in the two cases: The Dormitory's façade components were machine-made and needed full replacements several times, while Søkvæsthuset's human-made façades were incrementally maintained and repaired, leading lower material uses. While Søkvæsthuset's facade had a high up-front cost, its long lifespan offset costs over time and made it an economically viable low-metabolism design principle in a whole-life-cost perspective.

LEGIBILITY

The material complexity of the build-up of Søkvæsthuset's façade wall was low despite its many purposes/qualities relative to the Dormitory's in which the wall build-up complexity was significantly greater. When the façade contained only a few materials and used construction techniques that were well-known for centuries, its properties and upkeep were legible to centuries of users too. This is a design principle of a low material complexity, a minimum of layering of those components intended to last, and of legibility across time with the use of well-established construction methods.

MULTIPLE PURPOSES

Søkvæsthuset's façade served purposes across all four categories of lifespans in the BUILD-framework, whereas parts of the Tingbjerg Dormitory's façade had narrower purposes (i.e. only functional/technical) resulting in several replacements and a greater metabolism. Having multiple lifespan qualities or purposes at once is therefore a low-metabolism design principle.

#07

SINGULARITY

Søkvæsthuset's façade wall's qualities – its sculptural, rigorously ordered form, structural capacity, thermal properties, and maintainability – could not be separated into parts or layers like in the case of the Dormitory. The singularity and irreducibility of Søkvæsthuset's façade wall, in which no quality could be altered in part without also changing the whole, appeared to be a low-metabolism design principle.

CLEAR BOUNDARY

The clarity of the boundary of Søkvæsthuset, by shear mass and entangled lifespan qualities, made it reluctant to spatial expansion, unlike the Dormitory where the structural walls were perpendicular to the façade and where the façade itself consisted of elements communicating different and contradicting levels of permanence. The authoritative boundary, stubbornly resistant to change, is therefore an underpinning design principle for a low-metabolism design.

6. CONCLUSION

Based on previous quantitative findings of a large difference in metabolisms between a 270-year-old preindustrial case and an industrialised case of late Danish Modernism, this paper qualitatively analysed the entangled relationships between the different lifespan parameters of the BUILD-framework in the use-stage of the two buildings. A series of six design principles of low-metabolism architecture were identified to inform contemporary design of new buildings and adaptive reuses of existing buildings, including from the Modernist Period (1933-1974), to minimise needs for future material consumption. The use of these principles requires contextual, project-specific interpretations by architects to weigh trade-offs. There is a need for future research to study and interpret trends of metabolisms among a larger number of cases to contribute to theory on how buildings change with future needs, and what margins for change in buildings may minimise material uses, as well as to clarify how low-metabolism design principles may be adapted to a contemporary building culture's industrialised processes, material-palette, building codes, budgets, waste-handling, and CO2-emission goals, both in terms of up-front and whole-life carbon. ■

ABSTRACT

This contribution investigates how Docomomo Full Documentation Fiches could be adapted to everyday residential heritage and encourage circular renovations in marginalised territories (peripheral and socioeconomically fragile areas).
Existing buildings represent resources for cities but often constitute a degraded, obsolete, and energy-intensive asset. Before renovations, a significant step in shifting to a circular economy is collecting quality data about buildings. Documentation becomes a tool to interpret not only masterpieces but also everyday architectures and to introduce circularity in their analysis.

Docomomo has documented masterpieces using the Full Documentation Fiches (FDFs); these tools contain some specifications that exclusively address masterpieces and lack specifications about buildings' context in terms of circularity of local materials and stakeholders.

This research aims to provide a template to holistically document everyday residential heritage by: (1) adapting specifications from the original FDF template; (2) evaluating the architecture; and (3) mapping local materials and stakeholders to be involved in renovations.

First, the study selects in the marginalised inland Marche region (IT) three 1950–1976 housing projects not of renowned authorship but conveying a modern optimism. Second, the original FDF template is adapted to everyday heritage; an adaptation table identifies specifications not applicable to non-masterpieces and integrates specifications that address everyday housing and circularity. Finally, the adapted template is tested on the selected buildings by collecting information through additional tools (e.g., archival material).

The results are three adapted FDFs for the selected buildings which testify that Docomomo FDFs can be applied beyond masterpieces and widen knowledge about buildings' context. Adapting the FDF template represents an effective method to update the specifications with coherent justification. The adapted template could be digitalised and extended to other building typologies. The study envisions the adaptation of Docomomo's tools as an initial step to guide holistic documentation that suits circular approaches for everyday heritage.

1. EVERYDAY RESIDENTIAL HERITAGE AND CIRCULARITY

INTRODUCTION AND BACKGROUND

Existing buildings represent examples of resilience and resources for our cities.[1] However, everyday architectures—particularly of the second half of the twentieth century—often constitute a degraded, obsolete, and energy-intensive asset.[2] This requires practitioners to develop adequate tools to approach the built environment and to gain more contextual knowledge about buildings.[3]

Before renovations, a significant step in the transition to a circular economy is collecting quality data about buildings.[4] Through documentation, professionals gather data and produce inventories to understand and manage the built heritage.[5] Since the 1960s the Council of Europe has issued charters, conventions, and conferences to develop inventories that identify, interpret, and preserve historic buildings.[6] Besides addressing heritage buildings, documentation has also intertwined with the concept of circularity in tools such as the Building Circularity Passport® or the Building Renovation Passport. The former supports buildings' planning and documentation after finalisation.[7] The latter integrates the documentation of everyday buildings with a renovation roadmap.[8]

When investigating circularity, scholars have moved beyond buildings in cities and are now exploring peripheries, smaller towns, villages, and rural settlements.[9] Some of these contexts suffer from marginality due to demographic degrowth, abandonment, and weak services and infrastructure.[10] Undervalued and decayed buildings in these areas represent a chance to transform and upgrade spaces, infrastructures, and housing.[11]

The value of existing buildings—in this case, housing—has been addressed by the Frankfurt Declaration (2023). The signing parties of the Declaration, Docomomo among them, encouraged the investigation of twentieth-century housing masterpieces to design high-quality spaces, achieve climate goals, and respond to the housing demand.[12]

Within that framework, this paper explores how Docomomo can contribute to the circular transition through the elaboration of holistic documentation tools analysing residential architectures with their context. As recently demonstrated, existing residential buildings can be investigated from a heritage perspective by juxtaposing the terms "everyday" and "heritage."[13] This study adapts Docomomo's documentation tools to everyday residential heritage, embracing marginalised territories to encourage circular renovations. In conclusion, the tools' digitalisation and implementation in other building typologies are suggested.

2. TOWARDS A HOLISTIC DOCUMENTATION OF NON-MASTERPIECES

FILLING THE GAP IN HERITAGE DOCUMENTATION

Docomomo's founding intention as an organisation for the DOcumentation and COnservation of the MOdern MOvement was to document important modern buildings to be protected.[14] Since the early 1990s, Docomomo has designed an inventory of documentation tools known as "fiches."[15] At

present, three types of fiches are used: the Minimum Documentation Fiche (MDF), the Full Documentation Fiche (FDF), and the Good Conservation and Restoration Practice Fiche (GPF). The MDF and FDF respectively provide two degrees of documentation: a synthetic degree, offering basic information about buildings, and an extensive degree, evaluating the architecture and serving scientific research.[16] The GPF represents an evolution of the FDF to identify and document model approaches for preserving masterpieces. All tools contain specifications about the immediate surroundings of buildings but lack specifications about buildings' context in terms of circularity of local materials and stakeholders.

With the Eindhoven-Seoul Statement (2014) following the founding Eindhoven Statement (1990), Docomomo officially expanded its mission to include other territories, times, and perspectives, as well as topics of reuse and sustainability.[17] In elaborating an inventory of the architecture of the modern Movement and that of the twentieth century more extensively, Docomomo has encouraged the documentation of "both outstanding individual buildings and 'everyday' examples."[18] However, the fiches published by Docomomo's national chapters reveal that the documentation has been primarily carried out for masterpieces.[19]

This contribution addresses the gap in the application of Docomomo tools to everyday residential non-masterpieces of the second half of the twentieth century, as these buildings:

- feature modern traits such as new materials, absence of ornamentation, clean lines, low-pitched roofs, asymmetry but balance in composition, and transparent layers.[20]
- represent, among other building typologies, one case with which to test holistic documentation.

By addressing everyday housing projects that, until now, haven't undergone recent or substantial renovations, this study follows the documentation approach set by the fiches. The contribution advances knowledge in adapting the original FDF template to everyday residential heritage holistically, embracing its context. The adapted template becomes a tool to provide deeper information about everyday housing projects and to identify circular networks of resources for housing renovations. Moreover, circular renovations in marginalised contexts can boost local production and create employment and dwelling opportunities to counteract the condition of marginalisation.

3. UNVEILING THE POTENTIAL AND LIMITATIONS OF DOCOMOMO FDFS

3.1 CENTRAL QUESTION AND OBJECTIVES

This contribution investigates how Docomomo FDFs can be adapted to everyday residential heritage and become the basis for circular renovations in marginalised territories. The research aims to provide a template to holistically document everyday housing projects by:

1. Adapting specifications from the original FDF template: some original specifications address masterpieces (e.g., "status of protection") and

cannot be applied to everyday residential heritage. Additionally, original specifications lack the concept of circularity. The adaptation process identifies not-applicable specifications and integrates new ones.

2. Providing an evaluation of the architecture: the fiches describe masterpieces according to technical, aesthetic, and social perspectives. This research applies the same perspectives to everyday housing projects.

Mapping materials and stakeholders: the fiches include graphic mat3. erial as an attachment. In addition to plans, sections, and elevations, the adapted template will include maps at the territorial scale to identify local stakeholders and materials to potentially incorporate in renovations.

3.2 THE ADAPTATION PROCESS

This paper follows three phases to adapt the original FDF template to everyday residential heritage: (1) Selecting, (2) Adapting, and (3) Testing.

3.2.1. SELECTING

The first phase entails selecting a focus time frame, a study area, and three housing projects.

This contribution addresses the documentation of everyday housing projects realised in Italy from 1950 to 1976. The year 1950 is taken as a reference year for the housing reconstruction period after the post-WWII housing crisis;[21] 1976 represents the introduction of L.373/1976,[22] the first law in Italy regulating building energy consumption. Within this timeframe, the study focuses on the marginalised municipalities of the Appennino Basso Pesarese-Anconetano,[23] located in the central Apennines **(Fig. 1)**. The municipalities are small centres and rural villages of the inland Marche region.[24] They share similar features regarding urban development, degrowth, migration rates, infrastructure, tourism, and industrial production.[25] In one of them, Serra Sant'Abbondio,[26] through an information-oriented selection,[27] the study has selected three housing projects from 1950 to 1976 **(Fig. 1)**. The buildings were chosen because: (1) they are not of renowned authorship or a specific architectural style but they all convey a modern optimism; (2) they are characterised by the most heterogeneous features among the housing projects whose material was accessible in municipal archives (location, residential typology, construction date, authorship, and dwelling units). The three housing projects are:[28]

1. Housing project A (1965): single-family detached house;
2. Housing project B (1956): former school building, now single-family social housing with a community centre;
3. Housing project C (1974): two social housing blocks.

3.2.2. ADAPTING

To adapt the original FDF template to everyday heritage, this study has developed an adaptation table **(Fig. 2)**. The table identifies in the original FDF template[29] the specifications that do not apply to everyday residential heritage and integrates specifications that are more appropriate for everyday housing and that could link everyday heritage with circularity. The table classifies

25. "Consumo di suolo della Regione Marche," Regione Marche, accessed April 3, 2024, https://

the examined specifications as follows: (1) Not-applicable specifications, referring to not-significant or not-available information about everyday residential heritage (e.g., "status of protection"); (2) Critical specifications, providing additional information, often hard to obtain, about the building (e.g., "summary of important modifications after completion"[30]); (3) Integrated specifications, widening knowledge about the building with its context and introducing the concept of circularity (e.g. "land register data," "regional features"). The table justifies the classification with an explanation for each examined specification. Overall, eleven specifications are classified as not applicable, six as critical, and eleven as integrated. Finally, the classification guides the update of the original FDF template.

3.2.3. TESTING

In the last phase, the adapted FDF template is tested on the case studies. Additional tools that provide information about the architecture—such as archival material, 2D representations, photographs, and mapping—are applied to run the test in three steps: (1) collecting information about the housing projects; (2) producing graphic material from archive drawings; (3) filling in the specifications of the adapted FDF template with the collected information and the produced material.

4. DISCUSSION AND CONCLUSION

4.1 POTENTIAL AND LIMITATIONS

The test delivers three adapted FDFs **(Fig. 3),**[31] one for each case study. The resulting fiches highlight aspects for interpretation along with the potential of the adapted FDF template:

- Holistic documentation: the adapted template embraces the context and local resources related to buildings.
- Preservation of archival material: the adapted template can counteract the loss of archival material on buildings, currently in paper form and with no preservation measures.
- Dynamic and interactive documentation: the adapted template could be digitalised to gradually expand information about the building and share knowledge among involved actors.
- Extension of application: the adapted template could be applied to similar buildings in the study area and be further developed for global use. Furthermore, the adapted template can be applied to non-masterpieces beyond the residential typology.
- Community engagement: a more holistic documentation could introduce new specifications in the adapted template to express the assessment of the building by its users.

In addition to these potential uses, documentation through the adapted FDF template also encounters the typical limitations in dealing with tracking private and non-renowned buildings:

- Lack of information: local archives preserve limited material—mainly requests for building permits and drawings without construction details.

www.regione.marche.it/Regione-Utile/Ambiente/Cartografia-e-informazioni-territoriali/Repertorio#13046_Consumo-di-suolo-della-Regione-Marche.

26. Serra Sant'Abbondio was chosen as a representative town for the study area as the result of a random selection. Bent Flyvbjerg, "Case Study," in *The Sage Handbook of Qualitative Research*, 4th edition, eds. Norman K. Denzin and Yvonna S. Lincoln (Thousand Oaks, CA: Sage, 2011), 307.

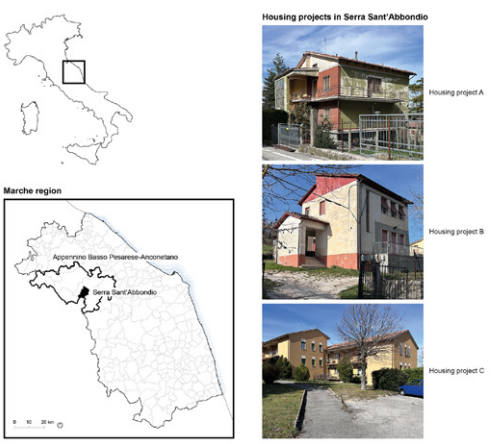
27. Flyvbjerg "Case Study,"

28. The buildings are described in Fig. 3 (QR codes).

29. Provided by Docomomo Italy.

30. The power of attorney is required to access private documents.

31. The documents are available in Fig. 3 (QR codes). Sensitive material is redacted or not included.



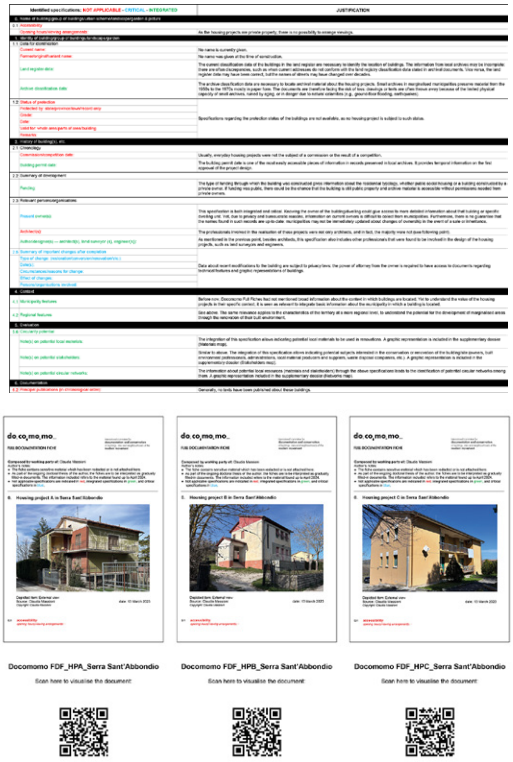


Figure 1. Case studies © Authors, 2024.

Figure 2. Adaptation table © Authors, 2024.

Figure 3. Adapted Docomomo FDFs © Authors, 2024.

- Limits related to approaching private owners:
    1. Accessibility of documents: the collection of information about the current features of buildings requires the power of attorney, granted by private owners, to access the real estate registry.
    2. Privacy: there are regulations regarding the publication of sensitive data related to the buildings—location, archive classification data, etc.—that need to be clarified. In the resulting fiches, this information is redacted or not included.

4.2 SIGNIFICANCE AND IMPLICATIONS

Adapting the FDF template through the adaptation table represents an effective method to update the specifications with coherent justification. Testing the adapted template on tangible case studies unveils the modern traits of everyday twentieth-century housing and hints at comparative observations. Housing projects A, B, and C represent diverse residential typologies, feature different architectural compositions, and suggest strategies for adaptive reuse. The resulting fiches testify that Docomomo FDFs are a flexible and adaptable tool that can be applied beyond masterpieces and widen the contextual knowledge about buildings. The identification of local resources—materials and stakeholders—sets the ground for circular networks to foster circular renovations.

In line with digital instruments applied to the analysis of the built environment, the digitalisation of the adapted template is seen as necessary to:

- improve the collection, correlation, and comparison of acquired information;

- engage administrations to ease access to private documents;
extend the application to other everyday building typologies.

The digital tool could include a standard layer—specifications for all everyday architectures—and an additional layer—customised specifications based on the building typology.

This study demonstrates how Docomomo, as a leading organisation in heritage documentation, can contribute to the circular transition in the built environment. The adaptation of Docomomo's tools constitutes an initial step to guide holistic documentation that suits circular approaches for various typologies of everyday heritage. ■

BIOGRAPHY

Claudia Massioni is a doctoral researcher at HafenCity University Hamburg (DFG research training group "Urban future-making"). After a high-school exchange year (Portland, OR), she completed a five-year master's degree program in building engineering and architecture at Marche Polytechnic University (Ancona, IT). During that, she joined the Karlsruhe Institute of Technology (Erasmus+). She developed her PhD proposal—about everyday housing in marginalised contexts—during a stay at Leibniz University Hannover (Institute of Urban Design and Planning). She is currently a guest researcher at TU Delft, Faculty of Architecture, collaborating with the sections Heritage & Architecture, and Theories, Territories, Transitions.

Wido Quist is an associate professor in Heritage & Technology leading the section Heritage & Architecture at the Faculty of Architecture and the Built Environment, TU Delft. He is the secretary general of Docomomo International and chair of Docomomo Netherlands. Since 2022 he is—together with Uta Pottgiesser—coeditor in chief of Docomomo Journal. Wido has been active in many national and international research and educational projects and has published extensively in the fields of construction history, adaptive reuse, and modern heritage. His research and teaching centres around the preservation and adaptive reuse of the twentieth-century built legacy.

Roberto Cavallo is an architect, associate professor, chair of the group Architectural Design Crossovers, and head of the section Theories, Territories, Transitions, Faculty of Architecture and the Built Environment, TU Delft. He is a member of the departmental research steering team and advisor to several PhD candidates. A Council member of the European Association of Architectural Education, he is a founding member of the Architectural Research Network ARENA. He has extensive experience in workshops, conferences, and keynote lectures, and in international academic and professional events. Since 2013 he has collaborated with the European Commission as a built environment advisor.

ASSESSING THE ENVIRONMENTAL IMPACT: OFFICE BUILDING REUSE AS A SUSTAINABLE ALTERNATIVE TO DEMOLITION

TAYLOR QUIBELL
CARLETON UNIVERSITY, MASTER OF APPLIED SCIENCE BUILDING ENGINEERING GRADUATE

MARIO SANTANA QUINTERO
CARLETON UNIVERSITY, PROFESSOR

ABSTRACT

Building reuse is key to sustainability, given its potential to conserve resources, reduce waste, and foster sustainable development. However, determining the precise environmental impact of existing buildings through the quantification of embodied carbon in structures remains a challenge in North America. This research addresses this by examining an existing office building under three scenarios: "doing nothing," "building reuse," and "new construction." Despite variability in results, findings indicate that choosing building reuse over demolition and reconstruction can mitigate the release of carbon into the atmosphere, emphasizing the need for standardized methodology, policies, and incentives.

Buildings contribute significantly to global greenhouse gas emissions, with operations accounting for 39%, split into 28% operational emissions and 11% embodied carbon. While operational emissions have been targeted for reduction, quantifying embodied carbon precisely remains a challenge. Thus, this research focuses on the crucial question: How can assessing environmental impact through embodied carbon quantification champion office reuse over demolition?

The study uses a case study of 360 Laurier Avenue West in Ottawa to measure embodied carbon in three scenarios. These scenarios were chosen to better understand the environmental implications associated with different choices.

The case study emphasizes the importance of measuring embodied carbon for the building industry and identifies the most suitable assessment tools and methods for existing structures. It sheds light on how input variations impact reliability and accuracy, exploring the significance of embodied carbon results, and the potential of adaptive reuse in addressing the environmental, housing, and office building crises. The research concludes by projecting these findings, illustrating how one test case can inform a portfolio of buildings, advocating for building retention and adaptive reuse as effective climate action strategies.

1. INTRODUCTION

Climate change, primarily driven by fossil fuel combustion, has resulted in a 1.1-degree Celsius rise in global temperatures since the 1800s, with recent decades recording the highest temperatures on record.[1] This warming trend intensifies environmental hazards such as droughts, sea-level rise, extreme weather events, and biodiversity loss, exacerbating global challenges like animal extinctions and human displacement.[2] The reality of climate change necessitates transformative actions that promote sustainable emissions development through adaptive reuse.

Canada, among the world's leading per capita emitters, has critical targets outlined in its Strengthened Climate Plan, aiming for net-zero emissions by 2050 and a 40%-45% reduction from 2005 levels by 2030.[3] Despite these ambitious goals, current efforts are insufficient, necessitating rapid transformation, robust policies, and effective incentives to mitigate the looming climate crisis. Without significant shifts in priorities and enforcement, achieving net-zero emissions by 2050 remains precarious.

1.1 THE ROLE OF EMBODIED CARBON IN THE BUILT ENVIRONMENT

Buildings are the largest energy users globally, contributing about one-third of global GHG emissions and nearly half of all energy emissions.[4] In Canada, the building sector is the third highest GHG emitter, responsible for 17% of total national emissions.[5] The building sector's emissions trajectory, projected to reach 12.6 gigatons of energy-related emissions by 2030, underscores the urgency of decarbonization efforts.[6] Efforts have focused on reducing operational carbon emissions from building operations and embodied carbon emissions has remained relatively unexplored.

Embodied carbon encompasses emissions associated with material production, transportation, construction, maintenance, and disposal, constituting 11% of total building emissions globally.[7] Unlike operational emissions that can be mitigated over time through energy-efficient renovations and renewable energy adoption, embodied carbon emissions are in place during building construction.

1.2 EXISTING OFFICE BUILDINGS

Embodied carbon in existing buildings is critical for sustainable development, particularly in the context of modern architecture and the argument for reuse. Many older office buildings in Canada, particularly post-war brutalist structures remain underutilized or vacant.[8]

After World War II, there was rapid economic growth and technological advancements that led to quick construction of contemporary office buildings. As businesses underwent expansion, larger companies started to decentralize their operations. New buildings were designed to adapt to these evolving needs, incorporating features such as open floor plans. Today, these buildings face high vacancy rates exacerbated by shifts in office work trends.

Repurposing these underutilized office buildings into residential spaces presents a dual opportunity to address urban housing shortages and reduce

8. UNEP, "The Six Sector Solution to Climate Change"

the environmental impact associated with new construction. Ottawa, grappling with high office vacancy rates and housing demand, serves as a poignant example of this conversion potential.

1.3 PROBLEM DEFINITION

The current state of office building vacancies in Canada, the climate and housing crisis, the lack of understanding of the impact embodied carbon has on climate change, and the scarcity of tools to measure embodied carbon of existing buildings, has raised the question of how can evaluating the environmental impact through embodied carbon quantification promote office reuse over demolition? It also raises a set of sub-questions, including:

- Why is measuring embodied carbon imperative for the building industry?
- Why is quantifying the embodied carbon of an existing brutalist office building a relevant test case?
- How could adaptive reuse of buildings aid in the environmental, housing and office building crises?
- Can measuring the embodied carbon of a single building be applied to a portfolio of buildings?

1.4 THE RISE OF UNDERUTILIZED AND VACANT OFFICE BUILDINGS

The COVID-19 pandemic significantly impacted post-war office buildings, with mandates for physical distancing. Many commercial properties couldn't meet these requirements, forcing remote work. Consequently, many companies adopted hybrid models, reducing their physical office footprints. Increased vacancy rates reflect this shift. A healthy office vacancy rate is 10%, but Ottawa's downtown vacancy was 12.5% in Q2 2023 (CUI), and CBRE Canada reported 13.6%. Colliers' 2022 report showed an 11% vacancy rate with two million square feet of vacant downtown space, especially high in Class B and C buildings at 18.7% and 18.9%.[9]

1.5 EMBODIED AND OPERATIONAL CARBON

Existing buildings already have embodied carbon from their initial construction, which refers to all greenhouse gas emissions emitted during material production and construction.[10] This includes emissions from material production, transportation, and disposal over a building's lifecycle.

Embodied carbon emissions occur primarily during construction, renovation, or at the end of a building's life. Initial embodied carbon, occurring during material sourcing, manufacturing, and transportation, constitutes a significant portion of these emissions.[11] Structural materials like steel and concrete, which typically make up a large part of buildings, contribute the most to embodied carbon.[12] In some cases, up to 80% of embodied carbon can be attributed to structural systems.[13]

Operational carbon, on the other hand, includes ongoing emissions from building operations such as fossil fuel combustion and electricity use.[14]

14. CLF, "1 - Embodied Carbon 101"

Together, these embodied and operational carbon emissions constitute a building's "whole life" carbon footprint.

1.6 EMBODIED CARBON ASSESSMENT METHODOLOGIES

The shift from operational carbon to embodied carbon in building assessments has spurred the development of tools and methods for conducting Life Cycle Assessments (LCAs). Existing methodologies primarily focus on new construction phases and often overlook the carbon impact of maintenance and replacement materials, which is crucial for prioritizing reuse in decarbonization strategies. Tools favour new construction due to readily available material data and a misconception that building new leads directly to net zero carbon.[15]

Measuring embodied carbon in existing buildings poses challenges such as incomplete life cycle data, inaccuracies in as-built drawings, and difficulty in locating material information.[16] Despite these obstacles, methodologies from new construction assessments can be adapted for existing buildings. Tools such as EC3, CARE Tool, and One Click LCA help professionals estimate GHG emissions to make informed decisions on construction materials and processes.

These tools streamline calculations using preprogrammed data such as Environmental Product Declarations (EPDs), carbon intensity factors, and location-specific information. At the core of these programs, a straightforward calculation to quantify embodied carbon is performed, multiplying the quantity of each material by the corresponding carbon factor for the life cycle being considered:

material quantity (kg) x carbon factor ($kgCO_2ekg$) = embodied carbon ($kgCO_2e$)

***Embodied carbon is measured in CO_2-equivalent and is based on the relative impact of a carbon dioxide on global warming, (its Global Warming Potential (GWP).*

2. METHODS

The methodology used assessed three distinct embodied carbon scenarios - the embodied carbon of the existing building if it were built today, evaluating the embodied carbon of the new components required for building reuse, and determining the embodied carbon associated with a newly constructed residential building.

The methods used were:

1. Case Study Selection

2. Data Collection - Building information was gathered from existing public documentation, site visits, interviews, and archives.

3. Framework Development - A framework for conducting an embodied carbon assessment for three scenarios, "do nothing", "reuse", and "new construction" was developed using previous case studies.

Assessment 1: Manual Calculation - Manually calculate embodied carbon and material quantities, then gather EPDs and GWPs for each component to manually calculate the embodied carbon.

Assesment 2: CARE Tool – Use the CARE tool to measure the embodied carbon associated with the scenarios for "reuse" and "new construction".
Assesment 3: One Click LCA - Calculate the embodied carbon of the "do nothing" scenario using the One Click LCA tool.

4. Experimentation and Application

5. Analysis

2.1 NARONO BUILDING OTTAWA, ONTARIO, CANADA: A CASE STUDY

When selecting a case study, it was imperative to look for a high rise building with the potential for residential conversion. Built between the 1960s-80s and constructed of reinforced concrete, these buildings have the durability, configuration and floorplates that are suitable for residential conversions.[17]

360 Laurier Avenue West in downtown Ottawa Ontario was selected. This building lends itself well to conversion as it has a rectangular floor plate, egress on both sides, underground parking, servicing, located in the core, and has a high transit score.[18] There is currently a development application in to renovate and convert it into residential use.

Known as the Narono building, is an 11-storey former Correctional Service of Canada office. Designed by George Edward Bemi and constructed in 1969 in the Brutalist style, it features massive concrete forms.

3. RESULTS

3.1 ASSESSMENT 1: MANUAL CALCULATIONS

SCENARIO 1:

The "do nothing" scenario was crucial for understanding the existing structure's embodied carbon. Focus was placed on quantifying embodied carbon in concrete and steel, readily available from as-built drawings, focusing on floors, structural columns, windows, and ceilings.

Each floor's system comprised an 8" reinforced concrete slab and carpet tiles. The concrete was chosen based on Ontario Industry Baseline 35 MPa ready mix GU concrete with 15% slag cement. Fabricated rebar steel content was estimated at 125 kg/m3, utilizing the North American Material Baseline GWP. Carpet tile GWP was obtained from EC3's database. Structural columns, approximately 352 in total, used the same concrete GWP with 400 kg/m3 of steel content. Window GWP averaged 136 kgCO2e/m2 from EC3 and One Click LCA databases for 360 units. East and west walls, parking walls, stairwells, and elevator shafts used CMU with GWP values from EC3's Ontario database. Reinforced concrete on north and south walls assumed a strength of 42 MPa with a GWP of 367 kgCO2e/m2. Ceiling tiles on floors two to nine used a conservative GWP from EC3. HVAC, plumbing, electrical, roofing materials, insulation, elevator systems, and interior partitions were excluded due to data availability.

Total embodied carbon was calculated at approximately 3262 tonnes CO2e, equating to 179 kgCO2e/m2 of GFA.

17. CUI, "THE CASE for CONVERSIONS Understanding Opportunities for Conversions of Office Space to Housing in Canadian Downtowns," n.d., https://canurb.org/wp-content/uploads/The-Case-for-Conversions-FINAL.pdf.

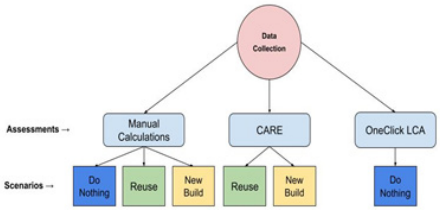
18. CUI, "THE CASE for CONVERSIONS Understanding Opportunities for Conversions of Office Space to Housing in Canadian Downtowns,"

SCENARIO 2:

The Narono building, with an embodied carbon footprint of 179 kgCO2e/m2, currently stands vacant and is being repurposed. Discussions with the development team revealed plans for extensive upgrades to mechanical systems. However, structural systems will be reused without lateral upgrades. Recycling and donation of interior elements is also planned. New interior finishes, partitions, and windows were quantified for their embodied carbon impact. The replacement of 360 inefficient windows with low-e clear glass and addition of 371 new windows were detailed. New ceilings using C and HAT channels with gypsum board, and interior partitions with steel studs and gypsum were also calculated from architectural drawings. The estimated embodied carbon associated with these changes, including demolition of precast panels for new windows, totals approximately 448 tonnes CO2e or 25 kgCO2e/m2 of GFA.

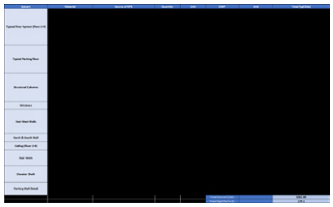
SCENARIO 3:

The "do nothing" and "reuse" manual calculations provide insightful results. They reveal that reusing the structure would result in 3262 tonnes of avoided carbon. While the embodied carbon associated with new building materials for reuse totals 448 tonnes of embodied carbon.



To better understand the significance of these savings, a comparison was made with a hypothetical new residential precast concrete building of the same size. To do this, the results from "do nothing", excluding windows, flooring, and carpet, plus the results from "reuse" were totaled. This equated to 2673 tonnes of CO2e or 147 kilograms of carbon dioxide equivalent per square metre of GFA. If this building were to be constructed today, it is important to note that the 3262 tonnes of CO2e associated with "do-nothing" would be lost through demolition.

ASSESSMENT 2: CARE TOOL



Manual calculations for embodied carbon in the "do nothing," "building reuse," and "new construction" scenarios provided a benchmark for comparison with CARE tool results.

The CARE tool requires users to input data into three tabs. The General Information tab includes project location, climate details, and electricity grid emissions. Buffalo, New York, was chosen for its climate similarity to Ottawa. The Existing Building tab involves inputting building characteristics, use, and energy data. The software defaults to Energy Use Intensity for energy and emissions since the building was unoccupied from 2019 to 2023. The Building Reuse tab includes information about reuse and any additional floor area. No extra floor area was added, but the use was changed to "Other Residential Lodging." Energy use reduction was targeted at 25%, and 24% was chosen for electricity produced on/off-site. Structural system reuse was set to 100%, with new insulation and finishes, and high-performance mechanical systems.

For new construction, the same dimensions and data were inputted, assuming low-emission concrete and high-performance systems.

New Systems	Material	Source of EPD	Quantity	Unit	GWP	Unit	Total (kgCO2e)
Windows	Clear Glass-low E coating	Offline Coated Glass EPD (Global)	1004.37	m2	12.5	kgCO2e/m2	12554.7
Ceiling	41mm C Channel	CLF North American Material Baselines - Cold Formed Steel Framing	29890.00	kg	2.44	kgCO2e/kg	72933.9
	22mm HAT Channel	CLF North American Material Baselines - Cold Formed Steel Framing	2475.00	kg	2.44	kgCO2e/kg	6039.0
	1 Layer of 13mm Gypsum	Conservative EC3 Data based on Global Averages	12518.06	m2	3.97	kgCO2e/m2	49690.7
Typical Interior Partitions in Units	1 Layer of 13mm Gypsum	Conservative EC3 Data based on Global Averages	9320.00	m2	3.97	kgCO2e/m2	37075.8
	Steel Stud	CLF North American Material Baselines - Cold Formed Steel Framing	49920.00	kg	2.44	kgCO2e/kg	121804.8
	1 Layer of 13mm Gypsum	Conservative EC3 Data based on Global Averages	9320.00	m2	3.97	kgCO2e/m2	37075.8
Typical Built-Up Floor	Floor Finish	CLF North American Material Baselines - Homogeneous Vinyl Flooring	12518.06	m2	8.84	kgCO2e/m2	110656.6
						Total(tonneCO2e):	447.84
						Total (kgCO2e/m2):	24.80

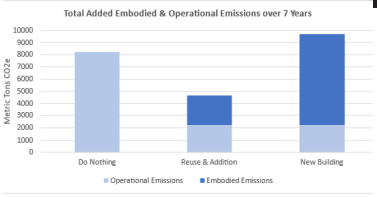


Fig.1: Methods for Assessing the Embodied Carbon of three scenarios. Credits: Taylor Quibell 2024

Fig. 5: Total Added Emissions over 7 Years. Credits: T. Quibell

CARE calculated 2450 tonnes of CO2e for reuse and 7465 tonnes for new construction.

ASSESMENT 3: ONE CLICK LCA TOOL

The CARE tool compares "reuse" and "new construction" but not "do nothing" scenarios. One Click LCA was used for assessing the reuse scenario, focusing on the carbon footprint of product and construction stages, such as raw material extraction, transportation, manufacturing, and installation. The assessment included inputting building information and material quantities from original drawings into One Click's material database. Adjustments were made for differences in available materials and declared units, converting volumes to kilograms when needed. One Click LCA auto-generates transportation distances and construction waste percentages. For existing buildings, initial site operations were challenging to determine and thus not inputted. The software processed the data, showing that ready mix concrete accounts for 34.8% of the total CO2 emissions. Results included graphs and pie charts, highlighting that floor slabs, ceilings, and beams contribute 33.3% to the GWP, helping identify materials with the most significant environmental impact.

One Click LCA calculated an estimated 3241 tonnes of CO2 equivalent for the existing building, which is equivalent to 178 kilograms of carbon dioxide equivalent per square meter of GFA.

4. PROJECTING THE RESULTS

Reusing the building would have the equivalent impact in lowering GWP as planting 130 -140 000 trees, removing 99 vehicles off the road, or eliminating the burning of over one million litres of gasoline.[19]

Reusing the structure also accounts for saving 957,811 kilograms of reinforced steel which is approximately the weight of 140 grown elephants.[20] Reusing also saves 14,180,640 kilograms of concrete which is equivalent to 545 truckloads of concrete.[21]

19. NRC, "Greenhouse Gas Equivalencies Calculator | Natural Resources Canada," Nrcan.gc.ca, 2020, https://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/calculator/ghg-calculator.cfm#results.

20. IFAW, "Elephant FAQ | How Much Do Elephants Weigh?," IFAW, 2021, https://www.ifaw.org/ca-en/journal/elephant-faq.

21. RMCAO, "Seasonal Load Restriction (SLR)," n.d., https://www.rmcao.org/wp-content/uploads/2021/09/RMCAO_SLR_Overview.pdf.

Statistics show that Ottawa has the most potential conversions in Canada due to the quantity of high and low-rise mid-century buildings. Of the building's studied, approximately 11 to 17 have the potential to be converted.[22] Assuming 11 of these are reinforced concrete structures, pursuing office conversions could potentially avoid 36 000 tonnes of carbon. The same projection can be made for Canada's Federal government who is planning on disposing ten buildings in the national capital region. Of these, 7 buildings could lend themselves well to conversion. Assuming these buildings have a similar embodied carbon value as the Narono building, there is potentially 23 000 tonnes of carbon embedded within the structures. Repurposing these buildings could have the equivalent impact in lowering GWP as planting one million trees.[23]

5. RECOMMENDATIONS

The findings of the study highlight the importance of reusing the Narono building and reveal the positive impact conversion could have on our environment. However, additional work needs to be done, such as:

1. Explore the development of a dedicated embodied carbon calculation tool for existing structures.
2. Propose policies mandating developers to quantify the embodied carbon of their existing building before proposing demolition.
3. Investigate the possibility of introducing carbon credits for salvaging building materials.
4. Monetize embodied carbon reductions through mechanisms such as carbon credits and tax rebates.

6. CONCLUSION

The research highlights the significant environmental benefits of reusing office buildings, specifically in the case of the Narono Building. It was found that leaving the building as is avoids 3252 metric tons of carbon emissions, reusing it produces 1449 metric tons, and new construction results in 6208 metric tons. The study extended these findings to estimate that reusing seven federal office buildings in Canada's Capital region could avoid 23,000 metric tons of CO2e, akin to planting one million trees or removing 7046 cars. The study concludes that standardizing methodologies, developing databases, and creating policies and incentives are essential. ■

CURTAINS FOR CROWN HALL: A BIOPLASTIC ADAPTATION

RYAN LEIGH ROARK
ILLINOIS INSTITUTE OF TECHNOLOGY

#07

ABSTRACT

This paper presents two installations at Mies van der Rohe's Crown Hall, on the campus of the Illinois Institute of Technology, one in Fall 2023 and one in Spring 2024. "Curtains for Crown Hall" (Pt. 1 and 2) serves as a test case for the use of tensile biomaterials in the adaptive reuse of Modern glass facades—both for aesthetic adaptation and to alter the performance of the glass. The biomaterials used in this installation were developed in 2023-24 by the author and have not been previously used in any architectural application.

While much testing remains to be done to assess the material's performance, the immediate purpose of this installation was to mitigate fatal bird collisions. Each migration season, hundreds of fatal bird collisions occur on Crown Hall's doorstep alone, and a billion birds are believed to die in glass collisions nationwide each year. While new glass technologies exist to deter collisions, older buildings must be retrofitted for deterrence. In protected buildings like Crown Hall, the glass itself cannot be replaced or altered—and the tenants of these buildings often eschew traditional drapery and window treatments—making a non-invasive temporary treatment like this installation an attractive alternative.

As the materials in "Curtains for Crown Hall" are made entirely from food industry waste, they are compostable and non-toxic—so while they are sturdy and reusable, if they are discarded, they will biodegrade quickly. Alternately, unlike traditional plastics, they can be reheated and remolded into new forms easily and without specialty equipment.

This paper finishes by discussing how Modernist glass buildings might be the perfect entry point for these novel biomaterials, long courted but ultimately dismissed by the architectural community, to play a viable role in buildings.

1. INTRODUCTION

Mies van der Rohe's Crown Hall was completed in 1956 to house the Illinois Institute of Technology's College of Architecture, where van der Rohe was the dean from 1939 to 1958. The building is considered a masterpiece of the Modern Movement and has National Historic Landmark status in the United States. Although van der Rohe is remembered largely for his use of glass and steel, Crown Hall is his only building whose visible structure is composed solely of glass and steel, and he called it "the clearest structure we have done, the best to express our philosophy."[1] According to anecdotes passed down from its original users, the building's original layout and systems allowed for reasonable thermal, acoustic, and visual comfort; however, with its significantly denser layout and contemporary HVAC systems, 21st-century Crown Hall is often far from comfortable by all these metrics, thanks to its extensive glass façade.[2]

In addition to concerns about energy performance and comfort, one of the building's great ecological tolls is to the migratory bird population each spring and fall as millions of birds fly through Chicago, which sits on a major migratory pathway known as the Lake Michigan Flyway. Despite the building's single-story stature, during migration seasons, Crown Hall's porches are littered with migratory songbird carcasses every day. The American Bird Conservancy estimates that a billion birds die in the United States alone every year due to collisions with glass windows and buildings.[3]

While new glass technologies exist to deter collisions, older buildings must be retrofitted for deterrence. In protected buildings like Crown Hall, the glass itself cannot be replaced or altered easily—and the tenants of these buildings often eschew traditional drapery and window treatments—making a non-invasive temporary treatment like this installation an attractive alternative.

This paper describes the development of two installations—one on the north face of the building in Fall 2023 and one on the south (primary) face in Spring 2024—whose immediate purpose was to mitigate fatal bird collisions **(Fig. 1)**. These installations use novel compostable tensile biomaterials developed in 2023-24 in the Roark lab at IIT using seafood industry waste products. The installations serve as a test case for using such experimental materials in the adaptive reuse of Modern glass facades, both for aesthetic adaptation and to alter the performance of the glass.

Crown Hall is, of course, just one representative—albeit quite a famous one—of a typology seen throughout Chicago and many cities across the world. In fact, while Modern buildings with extensive glass facades continue to define much of the Chicago skyline and streetscape, many of these buildings fall significantly short by contemporary standards for building performance, and they cannot always be permanently retrofitted—whether due to budgetary constraints or historic listing status, as in the case of Crown Hall.

Meanwhile, many novel biomaterials have failed to gain traction in the architectural community, despite initial enthusiasm, due to their semi-permanent nature and their unsuitability for long-term exterior applications—that is to say, they cannot stand in for primary structure or weatherproofing. In

the context of a building that already has structure and weatherproofing (but not much else), such materials may finally find their architectural purpose.

2. THE SHORTCOMINGS OF MINIMALISM

While few buildings are as strictly minimalist as van der Rohe's glass and steel buildings, contemporary energy conservation standards have conjured a minimalist ideal of the wall-that-does-it-all, with thermal insulation, waterproofing, air and vapor barriers, aesthetic finishes, and often structure all packaged tightly into one presumably hyper-efficient wall section. Passive House standards, among others, have bolstered the development of these wall types and the relatively airtight constructions that accompany them. Recently, however, this type of construction has faced critique, especially after the global Covid pandemic drew renewed attention to the importance of indoor air quality and open building systems.[4] More and more architects and educators have been revisiting lower-energy pre-modern building practices and even indigenous practices,[5] as well as new paradigms of circular economies and biogenic building practices, as evidenced by the popularity of books like Lewis Tsurumaki Lewis's *Manual of Biogenic House Sections* (2022), multiple open-access publications on circularity and "bio loops" by Arup, and myriad recent conferences focused on material provenance, embodied energy, and low-carbon construction.[6]

Arup's "Circular Economy in the Built Environment" (2016) is one of many publications to borrow a key diagram from Stewart Brand's *How Buildings Learn* (1994), illustrating the different layers of a building which age differently and have different expiry dates **(Fig. 2)**.[7] As Brand points out, buildings are often demolished prematurely if their systems (HVAC, plumbing, electrical, etc.) are "too deeply embedded to replace easily";[8] the same can be said of insulation, waterproofing, or any layer that becomes obsolete before the structure does. In developing his "six S's", Brand looked in turn to Frank Duffy, cofounder of British firm DEGW, who had previously identified four layers (to which Brand added *site* and *structure*). Duffy wrote that:

> *…there isn't such a thing as a building. A building properly conceived is several layers of longevity of built components…. Thinking about buildings in this time-laden way is very practical. As a designer you avoid such classic mistakes as solving a five-minute problem with a fifty-year solution, or vice versa.*[9]

As a highly protected historic building, Crown Hall's skin is sacrosanct, and its three shortest-lived S's—systems, space plan, and stuff—have been more closely protected than they would be in most buildings, accounting for some lag in meeting contemporary performance standards. For example, to this day students sit on backless stools, causing discomfort and orthopedic compromise, in the name of authenticity. There have been some necessary alterations over the years, including a 2005 renovation by Krueck and Sexton Architects and Harboe Architects, who refinished the steel, upgraded the single-pane glass

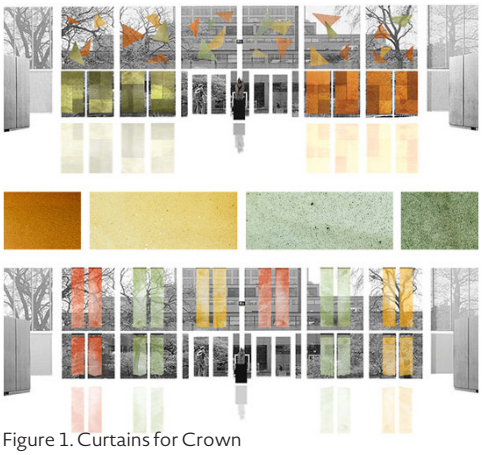
to double-pane, and restored the sandblasted glass originally specified by van der Rohe to the lower panels which had been replaced with a facsimile by SOM in a 1975 restoration.[10,11] However, the building's energy performance and occupant comfort continue to suffer in the name of Modernist beauty.

3. EMBRACING IMPERMANENCE

Perhaps counterintuitively, the imperative that interventions into protected historic buildings be reversible—that is, impermanent—makes them attractive candidates for the deployment of experimental biomaterials whose appeal lies in their biodegradability and cyclability. In most contexts, it is difficult for architects and non-architects alike to overcome the notion that a material needs a high degree of permanence to be used in a building, but here the new materials' ephemerality makes them more palatable to those known locally as the "Mies police", as the materials are clearly deferential in hierarchy to van der Rohe's glass and steel. For instance, when we first installed our biopolymer-based plastics on the north face of Crown Hall for an extended period, we faced no pushback because we could affirm that, even if the plastics stuck to the glass (which they did in places due to repeated heating and cooling), they could be detached with nothing more abrasive than hot water.

The materials used in the windows at Crown Hall were made using various combinations of two biopolymers: gelatin derived from fish skin and bones and chitosan, which is derived from the shells of crustaceans like shrimp, crabs, and lobsters. The plastics were dyed with a range of natural pigments, including blue and green spirulina (a seaweed product), red beet root powder, golden turmeric, crimson madder root, and green alfalfa extract, among others.



As the materials in "Curtains for Crown Hall" are made entirely from food industry waste and trace amounts of natural modifiers, they are compostable and non-toxic—so while they are sturdy and reusable, if they are discarded, they will biodegrade quickly. Unlike traditional plastics, they can be reheated and remolded into new forms easily and without specialty equipment. Despite their impermanence, these bio-curtains—and other analogous biomaterials one might introduce into the space—arguably do more to define the division between inside and outside than does the glass façade, at least along the entryways where all panels are transparent.

4. DEVELOPING NOVEL BIO≤MATERIALS

While tensile bioplastics are rarely deployed for architectural applications or at this scale, there are many makers worldwide experimenting and publishing open-access recipes for both tensile bioplastics, which are composed primarily of biopolymers, and compressive biomaterials, which also contain filler materials like agricultural waste, coffee grounds, biochar, or countless other organic materials. Most of this innovation can be attributed to product designers, industrial designers, fashion designers, and other makers of smaller-than-architectural-scale "stuff", to borrow Brand's term—and much of the work is shared openly through platforms like international crowd-sourced online database Materiom, where we started our research.

10. Sara Hart, "The Perils of Restoring 'Less is More'." *Architectural Record* (January 2006): 149.

11. Reversible additions by Dirk Denison Architects in 2013 made significant changes to the interior space planning for the first time, adding two sandblasted glass cubes inside van der Rohe's "universal space", to accommodate the administrative offices and three seminar rooms.

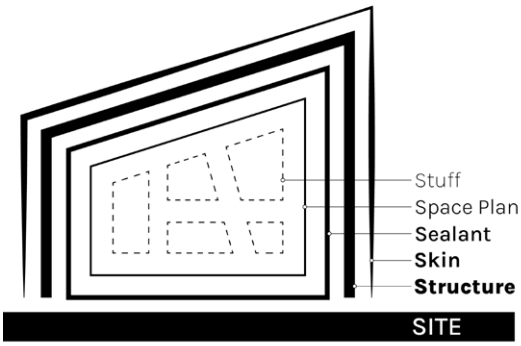


Figure 1. Curtains for Crown Hall Installations. Top: Collage showing Fall 2023 arrangement which was installed on the north façade in September through December 2023 (although both collages show the south façade). Bottom: Collage showing Spring 2024 arrangement which was installed on the south façade in May 2024.

Figure 2. The 'Six S" layers of a building, which all have different life spans, adapted from a diagram in Stewart Brand's *How Buildings Learn* (1994). Brand's diagram includes "Services"; here "Sealant" is added in its place.

The barrier to entry for the development of such biomaterials is low and the work to be done seemingly endless: we began by replicating recipes from the site that seemed likely to scale architecturally and that required only domestic kitchen equipment. From there, we hybridized recipes that showed promise and continued to refine those based on my observations of their performance. Some of the biopolymers we experimented with, which other bio-makers have developed much further, include seaweed-based polymers agar, alginate, and carrageenan; various forms of plant-based cellulose; starch-based polymers like tapioca; and fungal-derived chitosan. In the end, we decided to focus on materials made from a combination of gelatin and chitosan derived from fish, not only because they can be made from unavoidable food waste, but also because we found their properties most promising. Some properties we observed directly include tensile strength, heat resistance, water resistance, transparency (in the case of gelatin), moderate elasticity (in the case of chitosan), and near complete resistance to mold and bacteria. While we are still testing more quantitative performance metrics, literature indicates that these mixtures are also fire-retardant and compostable and should reduce UV penetration, as well as providing acoustic benefits and a degree of thermal insulation.[12,13,14,15]

5. DETAILING CURTAINS FOR CROWN HALL

Alongside the material development, it was critical to develop non-invasive means of attaching these new wall components to the existing structure of Crown Hall.

The first installation, which was designed in tandem with the development of the initial material recipe and all fabrication protocols, was initially designed only as a series of panels to cover the lower transparent windows along the entryway. As these windows are 7'-9" tall, the attachment detail was close enough to eye-level to warrant special attention to its concealment. Each of van der Rohe's windows is framed with extruded steel, separated from each other by a 1-inch-tall gap. For the lower windows we designed what we call the Mies Mullion Modifier (MMM), a 3D-printed plastic expansion screw that fits into the 1-inch channel and supports the hardware from which the curtains are suspended.

Once it was decided to use the bioplastics to deter bird collisions in Fall 2023, it became necessary to cover as much of the 11'-6" upper windows as fast as possible with our remaining stock of material. To this end of maximal coverage, we held a one-day workshop with volunteering students to teach them how to arrange triangular pieces of the material in planar tensile equilibrium using fishing line and hooks attached to magnets. The Spring 2024 installation is suspended entirely by the same magnetic hooks on both upper and lower windows.

Between August 2023 and January 2024, our casting capacities scaled up enough that, while our maximum panel size in Fall 2023 was about 2'x5', our Spring 2024 installation was crafted from 16'x4' bioplastic pieces, cut down based on the design. One other difference was that in Fall 2023, we created the full panels by heat-seaming the smaller cast panels, whereas in Spring 2024, the whole panels were single casts (spliced from two separate pours each, because the material becomes touch-dry quickly at our desired thickness)hile tensile bioplastics are rarely deployed for architectural applications or at this scale, there are many makers worldwide experimenting.

6. CONCLUSION: TRUE WALLS

Approximately a hundred years before the construction of Crown Hall, influential German architect and critic Gottfried Semper deconstructed the layers of a building in his *Four Elements of Architecture* (1851). Although his contemporaries would likely still think of walls in terms of masonry, which would provide structure, privacy, visual exclusion, and elemental protection, among other functions—their own pre-modern version of the wall-that-does-it-all—Semper, who was interested in frame construction, drew a stark distinction between structure and enclosure. In describing his prototypical building, as exemplified in a Caribbean hut he saw on display at the Great Exhibition in London in 1851, he affiliated the structure with the roof or frame, while he described the "true walls" as textiles which served the purpose only of defining enclosure (in versus out).[16] The other two elements cited by Semper were the hearth—the building's raison d'être—and the "mound" or elevated foundation which separates it from the ground.

Although Semper was describing what has since been described as a "primitive hut"—the most essential embodiment of architecture—he could well have been describing Crown Hall's plinth-like relationship to the ground and its massive roof trusses from which the visible structure of the building hangs. Whether the glass membrane can be considered Semper's "true walls" is more debatable: they provide security and protect from (many of) the elements, but they do not visually distinguish between inside and outside, nor are they reconfigurable to accommodate varying requirements throughout the seasons and days.

In this sense, many glass Modernist buildings might be considered lacking in Semper's premodern conception of enclosure—a temporally sensitive flexible means of defining different spatial occupancies—which has also become desirable in the pandemic era as open planning comes under question and architectural spaces are called upon to serve multiple

functions. Semi-permanent biogenic walls—whether tensile bioplastics or other types—are an attractive option for retrofitting these buildings without infringing upon their long-term identities, creating construction waste, or significantly adding to their carbon footprint. ■

BIOGRAPHY

Ryan Roark, AIA, PhD, is a licensed architect, writer, biochemist, and Assistant Professor of Architecture at the Illinois Institute of Technology, where she runs the Biomaterials Lab and directs the second-year undergraduate studio. She writes about the history of adaptive reuse, preservation, urbanization, and social constructions of solitude. Her work has been published in *JSAH*, *Studies in the History of Gardens and Designed Landscapes*, and the book *Ruskin's Ecologies* (Courtauld Books Online, 2021), among others. She has previously taught at Georgia Tech and Rice University. She has a PhD in research science from Cambridge University (2011).

HAS FOSSIL MODERNISM LED US TO A DEAD END?

#07

WOLFGANG H. SALCHER
FEDERAL MONUMENTS AUTHORITY AUSTRIA (BUNDESDENKMALAMT)

ABSTRACT.
Starting with a critical look at the fossil modernism that has led us into the climate crisis, the paper attempts to show the causes and history of the problem, along with the solutions that have emerged from the innovative power of modernism.

Fossil fuels provided a huge amount of energy. Crude oil, or 'black gold', and natural gas were cheap and easy to transport all over the world. The energy industry and resource-intensive construction industry benefited from this in particular. Modernist architecture also began its ascendancy at the same time as the boom in oil. However, nobody realised at the time what would happen as a result of cheap and reckless energy consumption and the construction that took place based on this. Modernism needs to be put into context and re-evaluated from this point of view, with a critical view taken from today's perspective. What can we learn from the mistakes made at that time?

In addition to concrete, steel and glass as construction materials, modernism also relied on extremely energy-intensive aluminium and plastic. Energy-intensive building systems posed a particular problem. Barnabas Calder's analysis "Form Follows Fuel", Vittorio Magnago Lampugnani's criticism of the use of resources in the construction industry and Werner Sobek's analyses of the construction industry and climate crisis are examined in an attempt to find solutions.

Simple approaches aimed at finding a solution are shown using examples from Vienna: Villa Beer (1931) by Josef Frank and Oskar Wlach, Wiener Stadthalle (1958), the Stadthallenbad indoor swimming pool (1974), Hotel Daniel (1959), Ernst Happel Stadium (1931/1959), the apartment of architect Margarete Schütte-Lihotzky, the Austrian Expo 58 pavilion (1958/1962) by architect Karl Schwanzer, and Wien Museum (1959) by architect Oswald Haerdtl.

Construction of the future needs to focus on preserving existing buildings, rather than reckless demolitions and constructions of new buildings as has been the case up to now. The longer a building exists, the more ecological it becomes. In addition to 'grey energy', the concept of 'golden energy' is also useful when it comes to conveying the idea of sustainable construction.

1. "BLACK GOLD" AND MODERN ARCHITECTURE

A critical examination of the fossil modernism that has led us into the climate crisis can help give us a better understanding of the history and causes of this problem. Understand, assess, act. A problem can only be solved once it has been analysed.

On the one hand, "fossil fuels made the world a much better place for humans", on the other hand, "we will make the planet apocalyptically horrible for humans" as a result of fossil fuels.[1] The abundance of crude oil provided energy in quantities that had previously been unimaginable and that could not have been achieved with human labour. Crude oil also meant that energy was no longer tied to one place, such as in the case of a water mill with its mill wheel. "Ever-larger oil tankers carried the world's new leading energy source around the globe with relatively low overheads, powering engines for a huge variety of purposes."[2] The energy could be shipped anywhere as a result and the cheap crude oil also made it possible to build a lot of beautiful and impressive constructions.

Modern architecture has broken with traditional forms and conventions. Barnabas Calder's analysis "Form Follows Fuel"[3], which states that modernity would not have been possible without environmentally harmful oil and gas, makes it clear to us, however, that this was also accompanied by another break with convention, which led to the large-scale use of fossil fuels and the building materials produced with these. It was no coincidence therefore that modern architecture - with its predominant use of steel, glass and reinforced concrete as building materials - began its ascendancy with the major break that followed from the use of fossil fuels such as coal, oil and gas.

Crude oil or 'black gold' has been one of the most important raw materials in industrialised society since the first half of the 20th century. Many of the innovations of modern times would not have been possible without petromodernity. New materials and technologies became possible and accelerated a whole range of processes. Modern architecture was only made possible through the availability of cheap energy. Hardly anyone at the time suspected the harm that might be caused as a result of the manner in which fossil fuels were changing the atmosphere.[4]

The analysis shows "how dependent we are on fossil fuels for our current standard of living and how comprehensively entangled our current architecture is with heavy use of fossil fuel energy."[5] Construction is "one of humanity's most energy-hungry activities".[6] This relationship between architecture and energy consumption is now subject to discussion once again, with the construction sector responsible for around 40% of CO2 emissions today. "The construction sector tops the list of material-consuming industries worldwide – and the demand for building materials continues to rise dramatically", says Werner Sobek in one of the key statements from his book 'non nobis – About Building in the Future'.[7] "A large share of energy consumption and emissions in the mobility sector is generated by transport in the construction sector."

"The fossil party is over", says Luisa-Maria Neubauer, a German climate protection activist, pointing to the energy-hungry construction sector up

until now. We must end the consumption of fossil fuels if we are to prevent catastrophic climate change.[8] The problems of global warming could be solved by switching from fossil fuels to renewable energies. "Solar, wind and other renewables will soon replace fossil fuels".[9]

2. EXISTING BUILDINGS ARE THE FUTURE

We need more renovations and adaptive reuse instead of demolition, therefore more 'demolition shaming'. We have solutions for the climate crisis through the tools of heritage conservation, such as resource economy, material continuity, minimal interventions, reversibility, use of natural construction materials, as well as preservation and repair before replacement. The focus is on preserving and complementing resources and on construction based on preserving our existing buildings and their value.

In addition to concrete, steel and glass as construction materials, modernism also relied on extremely energy-intensive aluminium.

2.1 ALUMINIUM

The small business premises 'Retti' in Vienna's city centre, which was completed in 1966, was Hans Hollein's first built property and marked the starting point for his famous architectural career. Hollein (1934-2014) received the Reynolds Prize in 1966 for these business premises with their aluminium façade and aluminium interiors in honour of an "extraordinary architectural achievement, with special use of aluminium".[10]

"Aluminium is used as the primary material because it is a true material of our century", Hollein writes in the architect's statement in which he described his project in 1966. The US company Reynolds Aluminum was the second biggest producer of aluminium in the USA and the third biggest in the world before it was taken over by competitor Alcoa in 2000.[11]

"The Reynolds competition was one of many tactics employed by producers to promote aluminium as the quintessential modern material. By publishing competition-winning works of aluminium architecture in marketing materials, producers enacted them (the architects) as 'silent salesmen'. The Reynolds award was largely a tool of competition between industry titans such as rival Alcoa, whereby architects and their projects were appropriated as a marketing medium", says Tait Johnson in his critical article on the history of the Reynolds Prize.[12]

Was modernism a marketing project by material manufacturers with the aim of seeking profit by influencing opinions and shaping the built environment? These types of architectural awards still exist today, whether they are for concrete, brick, metal, wood or other materials, and include aluminium architectural awards. Lobbyists from the respective interest groups try of course to position their product as the best and ecologically sound option. Greenwashing, which is also known as 'ecopornography', has been around for decades. Producing aluminium requires large amounts of electricity for the purposes of electrolysis from bauxite ore. A large part of the energy required to produce aluminium is still obtained from fossil fuels.

10. Honour awarded by the international jury of the American Institute of Architects (AIA)

11. China is now the biggest producer of aluminium by far.

12. Tait Johnson, "Marketing Modernism with the R.S. Reynolds Memorial Prize." In *2022 ACSA 110th Annual Meeting Proceedings, Empower, Conference in Los Angeles May 19-20 2022*, 432-438. ACSA Press, 2023.

The latest aluminium factories are located in countries with low energy costs, such as the United Arab Emirates, Bahrain, Saudi Arabia, Qatar (crude oil, natural gas) and Australia and South Africa (coal).

Aluminium represents a good option as a material due to its long service life resulting from its high corrosion resistance, as can be seen in Hollein's 'Retti' boutique, where the aluminium façade still looks new after almost 60 years.

The glass and aluminium curtain wall façade of Hotel Daniel in Vienna, which was previously the Hoffmann-La Roche building (1962), has barely aged even after more than 60 years. The good state of preservation is one of the reasons why Hotel Daniel is a rare international example of a property that has succeeded in substantially preserving its original curtain wall façade, including after a general renovation and conversion of the building, unlike for instance the glass curtain wall of the United Nations Secretariat Building (1951) or Lever House (1952) in New York City, which needed to be replaced.

2.2 ENERGY-HUNGRY BUILDING SYSTEMS WITH CONSEQUENCES

"The wonderful buildings of modernism were the very antithesis of everything that sustainable architecture needs to become: they gloried in profligate heating, cooling, ventilation and lighting systems, in new energy-hungry materials, in car-based cities and unlimited international air travel," is how Calder summarised this in his book.[13]

Our industrialised society of the 20th century and its achievements are inconceivable without the most important energy resource, namely crude oil. However, there are also considerable downsides that arise from these developments with this fossil fuel, including the fact that it is the main cause of global warming and also causes environmental damage when the oil is extracted and transported. The environmental damage caused by oil, coal and gas has not yet been taken into account in assessments of modernism. Oil has also had an impact on various other areas in addition to the construction industry, including mobility. Private transportation fuelled by oil, the 'carchitecture' of modernity, roads, motorways, parking spaces and car parks, underground parking areas, etc. involved huge changes to landscapes, urban planning and architecture.

Patterns of evaluation that are considered to be fixed and the values associated with these, including those of modernism, must be scrutinised and examined with a new and critical eye from today's perspective. The narrative of architectural history, in particular that of the 20th century, must be adapted to include a contextual framework and re-evaluation in the context of the environmental changes and damage that it has caused.

It is not about discrediting modernism, but rather learning lessons for the future based on the mechanisms and decisions from that time, in particular the hunger for energy and oil as the basis for many of the developments. The architects and the construction industry have a particular responsibility and duty in this regard.

It was only on the fringes of the mainstream that a small number of not yet influential figures began to question the relationship between architecture,

13. Calder, *Architecture: From Prehistory to Climate Emergency*, 446

humanity and nature.[14] These included Austrian artist Friedensreich Hundertwasser (1928-2000), who was an early champion of architecture that was both more in tune with nature and with humanity. He railed against the rationalism and functionalism of modern construction in his article 'Verschimmelungsmanifest gegen den Rationalismus in der Architektur' (Mouldiness Manifesto against Rationalism in Architecture)[15], which was published in 1958. Hundertwasser for a long time came under heavy criticism for his alleged populist funfair aesthetics, his 'façadism' and for being a 'prettifier'. The thoroughly visionary nature of Hundertwasser's philosophy of architecture in harmony with nature, ecological commitment and dedication to the preservation of mankind's natural habitat is only clear today.

3. POTENTIAL SOLUTIONS

Can the principles of modern architecture help us today, i.e. those of simplicity and minimalism, form follows function, use of new materials, openness and flexibility and integration of technology? The innovative power of modernism has the potential for helping to develop solutions.

3.1 SUSTAINABLE QUALITY OF LIVING

The pioneering apartment in Vienna[16] by architect Margarete Schütte-Lihotzky (1897-2000), which she designed herself and in which she lived from 1970 to 2000, has a large terrace with plenty of plants, greened façades, urban gardening and large awnings providing protection from the sun. The terrace is an important part of the apartment's holistic concept. Despite being only 55 square metres in size, the apartment (through its terrace) conveys a sense of being close to nature, which contributes towards the pleasant living environment and high level of quality for anyone residing there.

It is often not possible to implement standard energy-saving measures in modernist buildings of particular significance, such as thermal insulation for the exterior façades, as this would involve major changes to the building's character.

Following extensive investigations into restoration options and coordinated planning efforts, Vienna's famous Villa Beer (1931) **(Fig. 1)** by Josef Frank and Oskar Wlach will be comprehensively restored from 2024 to 2025 for the first time since its initial construction. The energy for the heating was originally supplied by coke, followed by crude oil. The elements used will include a heat pump, geothermal energy in the garden and photovoltaics on the flat roof in order to improve the Villa's energy footprint during future use without compromising the property. The original refurbished tubular radiators can be retained with this.

The recently renovated and expanded Wien Museum (1959) also uses a combination of photovoltaic systems and geothermal energy.

3.2 THE CONTROVERSIAL ERNST HAPPEL STADIUM IN VIENNA

Austria's national stadium, the Ernst-Happel Stadium (1931/1959) **(Fig. 2)** in Vienna's Prater public park is one of Austria's largest buildings. It was built

14. Calder, *Architecture: From Prehistory to Climate Emergency*, 414

15. www.hundertwasser.at, www.hundertwasser.com/en

16. 16 Franzensgasse, MSL-Margarete-Schütte-Lihotzky-Zentrum, www.schuette-lihotzky.at

between 1929 and 1931 for the second Workers' Olympiad based on a design by German architect Otto Ernst Schweizer (1890-1965). In addition to football matches, it also hosts major events that include concerts by Taylor Swift, The Rolling Stones, U2, Elton John and Bruce Springsteen, with capacity for up to 70,000 spectators. Discussions have been ongoing for many years about demolishing and rebuilding the stadium, even though it is protected as a building of historic significance. A right-wing populist political party in Austria and the Austrian Football Association (ÖFB) want to see the stadium replaced with a new and modern building. However, any new building would only host an average of six international football matches each year. The high costs of a football arena for just a few international matches per year have caused controversy for years. Interestingly, the media debate involving whether to demolish or rebuild the stadium has barely mentioned the ecological impact of any such project. Demolishing such a huge concrete building that has been proven to be intact and constructing a new one in its place seems absurd to many people during a climate crisis. There would be a huge amount of 'grey energy' (embodied energy) destroyed during the demolition process that would then also be required to construct a new building. The City of Vienna has decided to preserve the stadium, given that it has turned from a sports stadium into a concert arena and 93 per cent of its revenue comes from open-air concerts as a result of this. One of the largest photovoltaic systems in Austria with 12,000 photovoltaic modules was finally installed on the roof of the stadium in 2024. Geothermal energy is also being utilised with 270 boreholes and ground collectors adjacent to the stadium in the aim of converting it into a carbon-neutral sports facility and the first energy self-sufficient stadium in Europe. Plans are also being considered for a mobile roof structure that would allow the stadium to be used more frequently.

Photovoltaic systems are also in use at the legendary Wiener Stadthalle (1958) **(Fig. 3)**, the Stadthallenbad indoor swimming pool (1974) and the rescued Hotel Daniel (1959) in Vienna.

The Austrian Expo 58 pavilion (1958/1962) by architect Karl Schwanzer is one of the few pavilions still remaining from the 1958 World Exhibition in Brussels. After being relocated to Vienna, it has been used as a museum since 1962 and is a good example of adaptive reuse. An exemplary overall refurbishment that took place between 2008 and 2012 by architect Krischanitz allowed the building structure to be preserved and extended. A PV system was installed on the roof in 2024 in order to improve the energy footprint.

Architect and historian Vittorio Magnago Lampugnani also criticises the use of resources in the construction industry.[17] He makes a radical case for sustainable architecture while pleading against disposable architecture and the throwaway ideology of capitalism. Lampugnani criticises 'masking fundamentalism', i.e. the installation of insulation panels, and calls for an end to consumerism in urban planning and architecture. He talks about the short lifespan of new architecture and describes architectural projects as "short life toys", cheap and therefore less durable building designs and the "progressive obsolescence" in modernist architecture. He claims that this

introduced an excessive and reckless transient euphoria into architecture, particularly in the 1960s. He speaks of architecture as a transitory fashion item: "fast fashion" and "fast architecture", with the refrain "ending is better than mending". In addition to this, the commercial value of buildings also became detached from their material value. This led to demolitions after just a few years, even for buildings that were completely intact, because an even more profitable business could be conducted on the plot of land. People felt as though there was an abundance of energy during the period of the economic miracle. It was not until the shock of surging oil prices in the 1970s that heating and cooling systems started to become more efficient.

According to Lampugnani, this throwaway world and consumerism is the main cause of our environmental emergency. Not a case of demolishing and rebuilding, but renovating, unbuilding and expanding or transforming. The longer a building exists, the more ecological it becomes.[18]

4. GOLDEN ENERGY OF MODERN ARCHITECTURE

Modernist buildings also play their part in this regard, not simply by preserving the 'grey energy' that they contain, but also through their 'golden energy'. The concept of 'golden energy' aims to illustrate that existing buildings are made up of more than 'grey energy' and of more than the construction materials and emissions stored within them, since intangible cultural values are also linked in with existing buildings. Every location and every building has its own history, which is inextricably linked with the lives of the people who have lived, worked, learned, loved, played and celebrated there. The concept of 'golden energy' successfully reflects this cultural, social, atmospheric, emotional and creative added value of developing existing buildings. It reinforces the importance of architecture that creates an identity and of social sustainability as an urban resource.[19] ■

BIOGRAPHY

Wolfgang H. Salcher has been an architect at the Federal Monuments Authority Austria (Bundesdenkmalamt) since 2003. As State Conservator in Vienna, he is responsible for the preservation and conservation of buildings that include those by Otto Wagner, Adolf Loos, Jože Plečnik, Margarete Schütte-Lihotzky, Josef Frank and Hans Hollein. He worked at architectural offices in Austria, Italy and Germany, and at the Institut français d'architecture (IFA). He has taught at universities in Innsbruck and Vienna. Salcher has written publications on concrete conservation, postwar architecture and conservation management plans, and has organised international symposia on post-war modernism. He has been a member of Docomomo International since 2006.

CONCRETE LONG-SPAN BUILDINGS' ADAPTIVE REUSE: SUSTAINABLE RETHINKING OF PUBLIC ARCHITECTURE AND INDUSTRIAL HERITAGE

FRANCESCO ROMEO
DEPARTMENT OF STRUCTURAL AND GEOTECHNICAL ENGINEERING
SAPIENZA UNIVERSITY OF ROME

GIOVANNI MULTARI
DEPARTMENT OF ARCHITECTURE FEDERICO II
UNIVERSITY OF NAPLES

ABSTRACT

Twentieth-century large-scale public and industrial buildings are scattered worldwide fostering a wide debate in the fields of reuse, transformation, sustainable construction processes, and the ensuing balanced development of the involved urban areas. Redesigning a new life cycle for those buildings and their contexts that have lost function, use and significance provides a unique opportunity to contribute to making human settlements inclusive, safe, resilient, and sustainable (UN2030 Agenda, Goal 11). Among the buildings at risk, a prominent role is played by those in reinforced concrete in which well-known architects and engineers, set free from traditional structural requirements, introduced unprecedented, innovative solutions. In this realm, long-span buildings of the second post-war, such as sports and social facilities, warehouses, pavilions, hangars, markets, movie theatres, and auditoriums arouse considerable interest for their intertwined urban, architectural, and engineering significance. The awareness of their historical, cultural, and social values, combined with the serious and growing problems of structural safety, fuels today a greater sensitivity to this heritage. It is, therefore, worthy to protect and reuse these buildings as tangible evidence of a particular historical moment, rich in discoveries, novel construction techniques, and experiments on new materials. The issues of aging, poor energy, structural performance, change of function, use, and social role are amplified in this modern heritage, prompting the need for careful analysis and making its sustainable rehabilitation and reuse a demanding technical and economic challenge.

1. INTRODUCTION

The session aims to delve into methodologies geared towards the proactive protection and adaptive reuse of endangered or overlooked landmark reinforced concrete long-span buildings from the 20th-century cultural heritage. One of the hallmarks of this session lies in its multidisciplinary approach, which not only invites architects and engineers but also encourages collaboration across various fields to share recent approaches, studies, and interventions aimed at revitalizing these urban landmarks. The overarching goal is to transform these structures into catalysts for sustainable regeneration, thereby igniting cultural, social, and economic development within the communities they inhabit.

By reconceptualizing dismissed significant buildings as both cultural and economic assets, and by recognizing their potential for reuse and restoration within an integrated framework, a dual objective is achieved. Not only will their historical significance be preserved and enhanced, but their inherent resilience in the face of climatic and social changes will also be reinforced. Moreover, by reshaping their urban context, these buildings can reclaim their roles as vibrant hubs within their communities, contributing to the overall livability and vitality of the surrounding areas.

The session draws heavily upon the operational expertise and knowledge of the chairpersons, who have been actively engaged in the professional realm of the topic for several decades. Francesco Romeo, for instance, has conducted in-depth studies on the "Palazzetto dello Sport" in Rome, designed by Pier Luigi Nervi, and has contributed as a scientific consultant to its recent renovation (**Fig. 1**,**2**). Similarly, Giovanni Multari, through his professional practice at Corvino+Multari, has undertaken the renovation of iconic structures such as the Pirelli skyscraper, designed by Gio Ponti and Pier Luigi Nervi, at the onset of the previous decade (**Fig. 3**,**4**). Their hands-on experience will stimulate discussions and provide valuable perspectives on the complexities involved in the protection and adaptive reuse of modern heritage buildings.

2. KNOWLEDGE PATH AND SIGNIFICANCE ASSESSMENT

Long-span buildings can be considered emblematic of structural concrete architectural heritage assets. The scientific approach implied in the reuse of this building typology reflects the complexity of conservation, restoration, and valorisation policies requested for landmarks of modern architecture. The reasons are connected not only to a reduction or loss of serviceability and physical integrity often affecting such buildings, but also – and sometimes prevalently – to changing technologies, varying economic demand, market constraints, new regulations, and social and cultural modifications. Contemporary society is particularly sensitive to functional requirements and related legal responsibilities (as reflected in the progressive evolution and increase in codes and technical-administrative regulations), but much less to the preservation and re-elaboration of historical memory.

As sport and social facilities, warehouses, pavilions, hangars, markets, movie theatres, and auditoriums testify, long-span buildings are

a paradigmatic architectural context in which "form follows function". Therefore, the knowledge phase needs to be tailored to the features of this specific heritage asset. The gradual shift from traditional building materials such as brick, stone, earth, and timber, to concrete and steel that took place over the course of the twentieth century allowed to reach unusual free-span structures. So, reinforced concrete, whether in situ, precast, prestressed, or post-tensioned, warrants special attention as it has been used in countless ways to define a new architectural language. The challenge prompted by such large free-span buildings' spaces has led the designers to look for original innovative answers with pioneering technical proposals, often ad-hoc patented and experimentally validated through lab testing on scale models. The knowledge of these aspects plays a significant role to complement the on-site investigations and understand the technical underlying assumptions adopted by the designers.

The initial activity required by any adaptive reuse process for reinforced concrete long-span heritage buildings consists of gathering and analysing evidence enabling the assessment of significance. The latter is linked to the set of intangibles (social, historical, cultural) and functional properties, as well as to the structural envelope, that is, to the set of elements that connote their materiality (structures, materials, finishes) (ICOMOS-20C 2017, Diacodimitri et al. 2022).

The main objective of this knowledge phase is to investigate the original design, based on archive drawings and documents, the construction features, and the urban context of the building, with a special focus on the evolving historical background and social context. In addition, a massive survey campaign provides detailed information on the actual state of the building. The survey is aimed at developing a deep understanding process, allowing us to analyse, verify, interpret, and contextualize structural and architectural elements of the building. This survey would also allow us to delve into the comprehension of the intrinsic nature of these elements, for identifying transformations in time and variations from the original project as well as to provide documentary evidence of the current condition of the building. Due to the usual complex and extended volumetry, the survey project must deal with the necessity of integrating different survey methodologies and equipment. The whole survey shall be planned with the awareness of the structural elements' relevance. Therefore, the data acquisition operations must be aimed to obtain an accurate description of structural elements' geometries (Tostões and Ferreira 2016).

The data acquisition and processing phases lead to a reality-based (point cloud) 3D model; the latter could be adopted to develop a Heritage-BIM (HBIM) platform. The advantages offered by information management tools, combined with the possibility of gathering in a single digital database a multitude of generally scattered and fragmented data, make the HBIM a tool well suited for the multidisciplinary nature of a reuse project.

Once examined documentary and physical evidence, the knowledge path is enriched by the structural diagnostics phase to be implemented mostly relying on non-invasive methods (Non-Destructive Testing – NDT).

The knowledge path is also conducted on a sociological basis, aiming to establish a 'cultural, sociological and economic landscape' around the considered heritage site, analysing the role played by the building in the life of the urban context and how it is perceived by its inhabitants.

3. STRUCTURAL AND ENERGY PERFORMANCE ASSESSMENT

Based on the significance characteristics outlined in Section 2, the structural performance assessment of long-span heritage buildings of the 20th century must be rooted in their in-depth technical knowledge. Therefore, the assessment process for reuse purposes involves at first the retracing of construction history and techniques and the identification of the structural details. The physical conditions and structural integrity assessment and management are key prerequisites for any practical conservation and reuse policy. Therefore, the safety assessment, possibly including seismic vulnerability aspects, and structural retrofitting solutions must be carefully analyzed.

The structural conservation and rehabilitation process consists of a condition survey, identification of the causes of damage and decay, choice of remedial measures, and control of intervention efficiency. Each step is to be possibly conducted in compliance with cultural heritage general principles, namely minimum intervention, compatibility, and reversibility. The issue of the 'duration' of the material over time and the sources of degradation, nowadays accounted for by durability requirements and the 'service life' concept, must be dealt with since these aspects were not explicitly considered at the design time we are looking at.

Further investigations will be addressed to estimate the ideal response of the original intact structure concerning today's standards for live load values and combinations. Considering possible degradation aspects enables to estimate of the residual load-bearing capacity and gives indications about possible strengthening needs. According to ICOMOS/ISCARSAH Guidelines, and, more recently, fib Model Code 2020, preventive and proactive approaches shall be pursued for an effective through-life management strategy of this heritage asset (fib Model Code 2023, Di Re et al. 2021).

As far as the energy analysis is concerned, the best solutions for the construction of the digital twins of the buildings using BIM and BEM (Building Energy Modeling) techniques is identified optimizing the interaction of the two software tools in terms of the import of BIM into the BEM environment. The detailed physical model of the target building will be built paying attention to its history, intended use, and period of construction and the data collected during the survey activity will allow building both the BIM and the BEM models. To make the energy model as close as possible to the real building, calibration methods shall be implemented using the monitoring data. The calibrated energy model will firstly provide the current state of the building and secondly, it will be used to test various retrofit solutions compatible with the reuse concept. The aim is to find the best retrofit solution able to maximize the comfort of the occupants and

minimize energy consumption and retrofit costs (Stein 2010). Towards resource-efficient life-cycle planning, the vocation for the buildings' reuse related to natural light, ventilation, and passive climatic building envelope's solutions (presence or absence of solar devices, designed ventilation flows, proto-bioclimatic design elements, and components, including hygro-thermal multi-layered infill-walls) shall be thoroughly explored.

In essence, the ideal reuse project aims to embrace, on the one hand, the preservation of architectural features, on the other, functional updating, seismic adaptation/improvement, energy efficiency, MEP systems, the increase in the physical and technical performance of the envelope, the treatment of alterations, the relationship between the structural and architectural part.

4. RETHINKING, REDESIGNING AND REUSE

4.1. CONTEXT AND ANALYSIS

In embarking upon the journey of adaptive reuse for 20th-century landmark reinforced concrete long-span buildings, it is imperative to conduct a thorough assessment of contemporary needs. This entails a comprehensive understanding of the current socio-economic, cultural, and environmental dynamics shaping urban environments. Rapid urbanization, demographic shifts, technological advancements, and evolving lifestyle preferences all influence the demand for adaptable, sustainable, and inclusive built environments. By aligning adaptive reuse efforts with present-day needs, stakeholders can ensure that revitalized structures serve as relevant and functional assets within their respective communities.

Central to the contextual analysis is a commitment to conservation principles that prioritize the preservation of architectural heritage and cultural significance, especially in line with Docomomo's prescriptions. The conservation of modern heritage buildings extends beyond mere physical restoration to encompass broader considerations of authenticity, integrity, and contextual relevance, keeping in mind that many of these buildings worldwide are yet not listed as heritage due to the short historical span.

In response to shifting urban dynamics, adaptive reuse strategies offer innovative approaches to repurposing existing structures for new functions and purposes. These strategies encompass a range of interventions, including functional adaptation, spatial reconfiguration, and technological upgrades, aimed at enhancing the usability, efficiency, and sustainability of modern heritage buildings. From repurposing industrial warehouses into mixed-use developments to transforming historic theaters into vibrant cultural hubs, adaptive reuse offers a versatile toolkit for revitalizing urban landscapes while honoring architectural legacy (Smith, Johnson, and Garcia 2020).

Beyond the physical transformation of buildings, adaptive reuse projects hold the potential to catalyze social regeneration within communities. By fostering inclusive public spaces, promoting cultural activities, and supporting local economies, revitalized structures can become nodes of social interaction.

An effective intervention methodology for adaptive reuse integrates research, analysis, planning, and implementation phases to ensure a universal

and sustainable outcome. This methodology begins with thorough site assessments, historical research, and stakeholder consultations to inform strategic decision-making and design development. Subsequent phases involve conceptual design, feasibility studies, regulatory compliance, and project management to guide the execution of adaptive reuse initiatives with efficiency and precision. Throughout the process, a collaborative and iterative approach encourages flexibility, innovation, and responsiveness to evolving project requirements and community aspirations (Adams, Roberts, and Garcia 2018).

In addition to functional adaptation and aesthetic restoration, attention to repair actions and structural integrity is paramount in ensuring the longevity and safety of adaptive reuse projects. Structural assessments, material testing, and retrofitting interventions may be necessary to address age-related deterioration, seismic vulnerabilities, and environmental impacts. By investing in proactive maintenance and conservation practices, preservationists can safeguard the structural integrity and resilience of modern heritage buildings, ensuring their continued relevance and viability for future generations.

4.2. DESIGN STRATEGIES

Many attempted to draw an atlas of best practices for such interventions, nonetheless, it appears hard to state a precise list. However, it is surely by embracing mimesis, overlapping, completion, juxtaposition, substitution, opposition, dialogue, inclusion, and distinguishability that architects can think of adaptive reuse projects that honor the past, respond to the present, and inspire the future. Through thoughtful integration of historical context, innovative technologies, and community engagement, adaptive reuse projects can become catalysts for sustainable development, cultural enrichment, and social cohesion within urban environments. Within the session, selected interventions will undertake the strategies of adaptability (Garcia, Smith, and Brown 2018). For instance, upcycling materials offer a sustainable approach to construction by repurposing existing elements, such as prefab beams or columns, and giving them new life in different projects. By relocating these structural components, architects and designers can not only reduce waste but also imbue new constructions with a sense of history and character. This practice not only promotes circularity in the construction industry but also fosters creativity and innovation in design.

Mimesis, or imitation, involves the reinterpretation of historical forms, materials, and typologies within contemporary design frameworks. By echoing the architectural language of the past while incorporating modern amenities and technologies, designers can create spaces that resonate with historical continuity while meeting present-day needs.

Overlapping design strategies involves the layering of new interventions onto existing structures in a manner that respects their intrinsic qualities and spatial narratives. Rather than imposing singular design gestures, overlapping embraces the richness of architectural palimpsests, allowing historical and contemporary elements to coexist and interact synergistically.

Dialogue strategies emphasize the importance of collaboration,

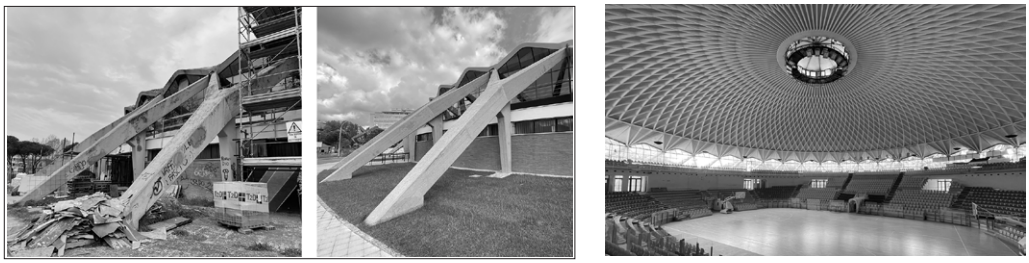

Figure 1. A. Vitellozzi and P.L. Nervi, Palazzetto dello Sport, Rome, Italy, 1956-57. Listed in 2021, the Palazzetto underwent conservative restoration works that ended in 2024. @ F. Romeo

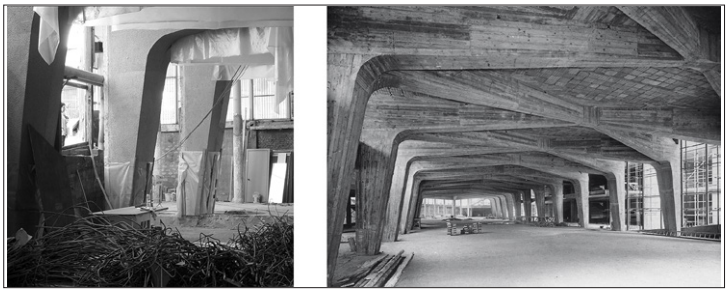

Figure 2. A. Vitellozzi and P.L. Nervi, Palazzetto dello Sport, Rome, Italy, 1956-57. The Palazzetto after the recent restoration works. @ F. Romeo

Figure 3. G. Ponti and P.L. Nervi, Pirelli Skyscraper, Milan, Italy, 1955-59. Left: Auditorium during the 2002-2005 restoration works, @ Archivio Corvino+Multari. Right: Auditorium during construction @ Archivio Pirelli.

communication, and community engagement in the adaptive reuse process. By fostering dialogue between stakeholders, designers, and residents, adaptive reuse projects can reflect diverse perspectives, values, and aspirations.

Substitution strategies entail the selective replacement or augmentation of existing building components with contemporary materials, systems, or technologies. This approach allows designers to address functional obsolescence, structural deficiencies, or environmental constraints while preserving the overall character and integrity of the original structure (Lee, Martinez, and Johnson 2022).

Distinguishability strategies emphasize the importance of preserving the distinctiveness and identity of modern heritage buildings within the urban landscape. By highlighting their unique architectural features, cultural significance, and historical narratives, designers can ensure that adaptive reuse projects retain their intrinsic value and character.

5. CONCLUSIONS

The journey toward adaptive reuse of 20th-century landmark reinforced concrete long-span buildings is complex, requiring a holistic approach integrating technical expertise, historical insight, and community involvement. This session underscored the significance of multidisciplinary collaboration among architects, engineers, historians, and community stakeholders to develop innovative solutions addressing both technical and socio-economic challenges.

Key to the success of adaptive reuse is a commitment to conservation principles prioritizing authenticity and contextual relevance. Balancing preservation with contemporary needs ensures revitalized structures become sustainable assets within their communities. Design strategies emphasizing historical reinterpretation, collaboration, and architectural identity are pivotal in creating projects that honor the past while meeting present demands and inspiring future developments.

Ultimately, proactive protection and adaptive reuse offer not only technical challenges but also opportunities for cultural enrichment, social cohesion, and sustainable urban development. Through collaborative and inclusive efforts, these iconic structures can continue to catalyze positive change for generations to come. ■

WHAT IF? OPEN QUESTIONS AND DESIGN SCENARIOS ON THE UPCYCLING OF LONG-SPAN STRUCTURAL COMPONENTS FROM 20TH CENTURY AUTHORIAL ARCHITECTURE

ALBERTO BOLOGNA
SAPIENZA UNIVERSITY OF ROME

MARGHERITA MAUREA
FEDERICO II UNIVERSITY OF NAPLES

ABSTRACT

This paper delves into the urgent priority of energy saving in building contemporary architecture, particularly focusing on the environmental impact of demolishing 20th-century long-span reinforced concrete structures. The study ponders an upcycling process as a promising solution in reusing existing structural components in new constructions to reduce resource waste and pollution. Rooted in the "Design for Disassembly" principle, the research explores the theoretical implications of disassembling, remanufacturing, and reassembling structural elements also in the heritage field, extending the theoretical implications of tectonics in architecture.

Drawing from existing literature, the paper discusses good practices of salvaging architectural elements, emphasizing the need to preserve valuable heritage through pragmatic disassembly and reassembly processes; furthermore, it aims to deepen the transformative potential of upcycling while addressing ethical, methodological, and design challenges.

The investigation highlights the criticality of concrete structures' demolition in today's construction industry and advocates for a circular construction approach that prioritizes reusing building components. Through two case studies of Pier Luigi Nervi's not-heritage-listed industrial architecture, the paper questions the fate of abandoned structures and proposes an upcycling process as a means to preserve both material and intangible heritage. Nervi's innovative approach to prefabrication serves as a model for integrating structural correctness with aesthetic expression, offering insights into the potential of upcycling long-span structural components for the design of new buildings, thus preserving the memory of construction techniques and architectural spaces. Beyond environmental benefits, the "Design for Disassembly" approach and upcycling process facilitate the transmission of cultural heritage, foster local value chains, and inspire innovative design solutions.

This paper is part of the results of an ongoing research project named *Upcycling Architecture in Italy. Forging and Promoting a Renewed Building Culture*, funded by European Union-NextGenerationEU (PRIN 2022 PNRR) of which Alberto Bologna is the Associate Investigator for the Sapienza University of Rome research unit. The paper structure and narrative are the result of the combined work of the two authors: Alberto Bologna and Margherita Maurea consider their individual contribution to the paper with an equal percentage of 50%.

1. INTRODUCTION

This paper aims to explore the ethical, methodological, and design implications of upcycling long-span structural components from 20th-century authorial architecture.

In the contemporary architectural scene, the issue of saving and optimizing energy resources emerges as an undeniable priority. Particularly, the demolition of reinforced concrete structures poses a problematic critique to be addressed, given its relevance in terms of global environmental impact.

The interest towards upcycling practices, in line with current governmental agendas and regulations, emerges as a promising response to this challenge. Upcycling understood as the process of reusing/remanufacturing pre-existing structural components in new constructions, could represent a significant opportunity to reduce resource waste and pollution stemming from cement production. However, this approach raises a series of questions, especially when it involves buildings designed by architects celebrated by historiography.

This research is based on a methodological premise rooted in the "Design for Disassembly" principles,[1] as well as in the "Assemblage Theory,"[2] provided by the American philosopher Manuel De Landa, which prompts us to reflect on how the use of disassembly and reassembly of structural elements can further fuel the concept of tectonics in architecture, a theme with deep roots in the design discipline's history.

Works such as Kenneth Frampton's "*Studies in Tectonic Culture"* have examined the relationship between construction, form, and architectural meaning, highlighting the transition from technical necessity to spiritual expression through construction.[3] The notion of assemblage adds another dimension to this reflection, pushing beyond the traditional concept of tectonics as a design tool.

This theoretical framework will be extended through a critical examination of two case studies of Pier Luigi Nervi's work: indeed, this research aims to provide insights into the transformative potential of building components' reuse while promoting a deeper understanding of its implications for architectural practice and heritage conservation.

This research aligns with the rise of "Design for Disassembly" and upcycling as energy-saving strategies in national and supranational regulatory frameworks, in the global construction industry as well as in academic research. However, while professional, entrepreneurial, and academic initiatives are exploring the potential of building components' reuse, it remains not yet explored the possibility of applying this approach to the context of architectural heritage, in figuring out the future of authorial architecture.

2. EXTRACTING STRUCTURAL COMPONENTS FROM LARGE CONCRETE STRUCTURES

Reinforced concrete constitutes a significant portion of the load-bearing structures in existing and new buildings. However, its manufacturing processes and extensive use contribute significantly to environmental

3. Kenneth Frampton, *Studies in Tectonic Culture: The Poetics of Construction in Nineteenth and Twentieth Century Architecture* (Cambridge: MIT Press, 1995).

impacts, including waste streams, global warming, depletion of raw materials, and destruction of natural ecosystems.

Buildings are increasingly being demolished after shorter service lives, driven more by the obsolescence of their functionality than by structural decay. This wastes resources and worsens environmental degradation, as cement production emits global emissions.

Disposable construction fails to acknowledge the significant economic and environmental advantages of reusing building components, giving them a new lease of life even after minor modifications can improve their performance.[4]

To address these challenges, there's a growing interest in adopting upcycling practices, in line with all current government agendas.

Circular strategies prioritize refusing, reducing, repairing, and reusing materials before recycling them, giving new usage cycles to the building stock, thereby allowing their lifespan to be exploited fully.

In the technical literature, the term "upcycling" subsequently established itself in the construction industry for the reutilization of components, irrespective of their function on the new site and once they are reconditioned and perfected in their performance, as distinct from "recycling", which merely describes the recovery of materials,[5] often falling into what has already been referred to as "down-cycling."[6]

In 1994, Joseph Alchermes analyzed ancient legal documents, particularly *De operibus publicis* (*On public works*) from the Theodosian Code,[7] showing an ethical approach to reusing materials from the Roman Empire's end.

Demolition was allowed only for irreparable damage, requiring carefully dismantling and salvaging as many components as possible for future use. Thus, deconstruction is portrayed not as a final option, but as a deliberate measure essential for the maintenance of buildings approaching the end of their life cycle.

Nowadays, the reuse of concrete components is not a novel approach: initiatives such as the business of the Belgian company RotorDC Deconstruction & Consulting and the research activities of the Structural Xploration Lab of the École Polytechnique Fédérale de Lausanne (EPFL), demonstrate the feasibility and potential of reusing precast concrete elements from obsolete structures and integrating them into new buildings.

These experiences show a variety of elements, ranging from small blocks to large slab elements, confirming that reusing concrete components significantly diminishes the initial global warming potential of new construction. This sets a new lower-bound benchmark for sustainable, circular construction.

In this regard, the K.118 building stands out as a significant best practice. Located in Winterthus (Switzerland): K.118 tangibly illustrates how even ordinary pieces of buildings can find new meaning. These kinds of examples represent a fundamental path for best practices, highlighting how the approach to reuse and upcycling is gradually spreading into practical applications as well. The implementation of the K.118 project demonstrated that reuse is a concrete path that can quickly lead to this goal.[8]

Through a practice of material reuse, buildings themselves are considered repositories, not just of materials but also of knowledge and past practices that might find new applications, becoming part of new value systems. Apart from collecting information and producing overviews of design development, this design approach seeks to find out which elements of this historical production lend themselves for reuse and re-assembly. This question is also intended as a provocation to trigger a debate on the value and role of history and the archive in contemporary off-site reuse practices and architectural design. Not only does this approach touch on urgent questions on the rationalization of building components and materials, but it also implies a need for a different view of history and historical production as a resource for innovation.

3. RETHINKING HERITAGE: THE 20TH CENTURY INDUSTRIAL ARCHITECTURE AND NERVI'S DESIGN PHILOSOPHY

Despite their historical significance and architectural quality, a significant number of industrial buildings from the 20th century are now abandoned, also in Italy: the causes lie in the difficulties in identifying potential uses, balancing functional needs with conservation imperatives, and the high costs of restoration and adaptation. A question follows: is it better to accept the inevitable state of uncontrolled ruin of architecture, or is it legitimate to rethink a new life for it by dismantling and reusing its components through an upcycling process?

In his work "*Histoire matérielle du bâti et projet de sauvegarde*", Franz Graf addresses the theme of contemporary architectural heritage by proposing an approach based on the material history of construction and preservation projects. He emphasizes the need to merge history with construction practice, stating that "the connection appears inevitable for architects and engineers working on existing structures", especially those of historical value.[9]

Such a design approach relies on a deep understanding of the historical value of the building by drawing on the recent history of materials and construction systems.

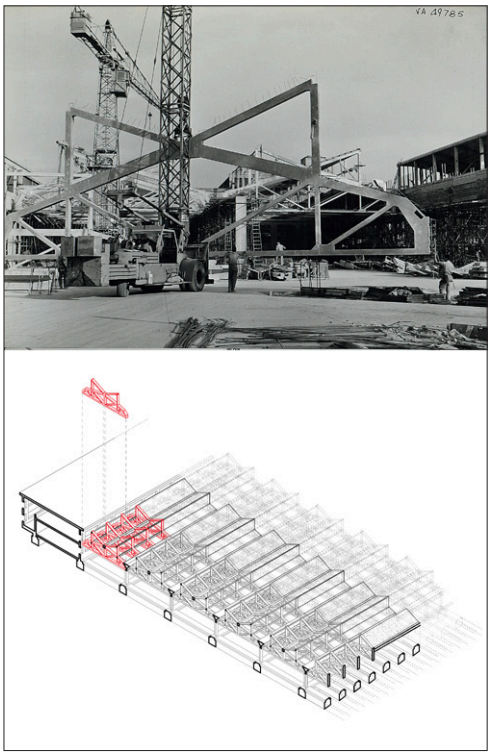
The objective of applying "Design for Disassembly" and upcycling processes to 20th-century concrete industrial architecture is to open questions essential for the management of a built heritage whose future is difficult to guarantee if the design approach is limited to the change of its intended use.

One exemplified through the industrial architecture built by Nervi: in questioning the future of his not-heritage listed buildings in the Mirafiori plant (1954-1955) in Turin or the Fiat Cromo plant in Venaria Reale (1962-1963), can the dismantling and reuse of their prefabricated structural long-span components be understood as an action aimed at the future transmission of both the construction techniques and the distinctive spatiality of Nervi's design approach? How will such an approach influence the design process and its implications on spatial configurations using these structural components? In the future, could this be considered a new form of heritage? Finally, from a purely technical point of view, what upcycling practices might

9. Franz Graf, *Histoire matérielle du bâti et projet de sauvegarde. Devenir de l'architecture moderne et contemporaine* (Lausanne: EPFL PRESS, 2014), 11.

be the most suitable to allow (also on a regulatory level) the reuse of these structural elements without them losing their original feature and character?

As known, Nervi was one of the most influential structural engineers on the international scene of the 20th century. He was renowned for his engineering audacity, architectural creativity, and entrepreneurial pragmatism directly carrying out building sites in Italy with his construction company Nervi & Bartoli.



Around structural prefabrication, Nervi conceived his constructive systems by applying the very concept of tectonics (intended as the art of assembly): indeed, his structures are always composed of on-site precast components that are subsequently assembled to shape domes, vaults, or long-span roofs obtained by the serial repetition of trusses.

Nervi & Bartoli achieved a remarkable feat in 1954-55 with the rapid construction of the northern extension of the Fiat industrial plant in Turin, demonstrating the efficacy of his prefabrication techniques: he used sliding scaffolding with frames fitted with ferrocement forms onto which he could cast in place the structure, and for the other storeys, where the beams only rested on the ends, he used T-beams prefabricated through ferrocement moulds (**Fig. 1**).

Nervi's mastery extended to incorporating ferrocement alongside reinforced concrete, employing advanced casting and formwork techniques to ensure an effective economy of execution. An example is the construction of the Chrome Plant for Fiat in Venaria Reale in 1962-63 (**Fig. 2**). Using a pneumatic system for concrete transport and special machinery for creating concrete subfloors, Nervi & Bartoli prefabricated various components, including the colossal roof trusses and infill panels, while managing their construction site. These "minor" and now, not-listed works conceived by Nervi show interesting applications in which design considerations were not merely aesthetic or functional but instead met specific technical and economic requirements. In both cases, Nervi's innovative approach to prefabrication, combined with the specialized lifting tools he devised for installing the beams, allowed for rapid construction and great quality.

However, despite their initial functionality, these complexes now find themselves partially decommissioned or at the risk of being totally or partially demolished, due to the current industrial policies of the owner who has moved car production away from Turin over the years.

Is there any alternative to the real risk of the total loss not only of architectural heritage but also of the legacy of Nervi's constructive intelligence? Such circumstances present an opportunity to salvage existing building structural components and reuse them for new ventures, certainly activating a process of saving energy and resources to produce new ones. This pragmatic disassembly and reassembly align with Nervi's design and building philosophy. Here, then, the upcycling process would make it possible to also preserve the intangible heritage of ideas, as well as architectural spaces (precisely generated by the assembly of prefabricated components) that can be admired in other circumstances in the future.

4. CONCLUSION: OPEN QUESTIONS – OPPORTUNITIES AND HERITAGE FRONTIERS IN AUTHORIAL ARCHITECTURE

The practice of reuse and upcycling of building components is not only about saving resources and embodied energy but also about preserving valuable intangible heritage.

When we consider the fate of the structural components of buildings, we cannot ignore the fact that they harbor legacies of craft expertise and of historical values and traditions.

In this sense, behind disused industrial buildings such as those discussed above, lies the legacy of the constructive intelligence of designers like Nervi, which is in danger of fading with them.

In 1947 Nervi summed up his design philosophy into two words, *Corretto costruire*, that is "to build correctly", Nervi's essence of architecture. Structural correctness is linked "with the requirement of the technology and statics, economic and functional truthfulness,"[10] and is a necessary and sufficient condition of satisfactory esthetic results.

For Nervi, this working method assumed above all a rigorous, creative, rational approach, with a continuous critical constructive focus which produced a plastic and formal result in a balanced and harmonious whole, which became a new kind of beauty.

In this context - as also Kenneth Frampton argues - tectonics is not simply a matter of construction technique but rather a complex articulation that integrates structure, material, and formal expression.

10. Pier Luigi Nervi, "Corretto costruire", in *Strutture. Rivista di scienza e arte del costruire*, no.1 (April 1947), 4-5.

Nervi's practice in the field of prefabrication has shown that the monolithic qualities of his concrete structures are derived from a construction concept that is achieved through the assembly of individual components.

From a speculative point of view, Nervi's approach stands out for the progressive use of structural components, which, while different in each project, are characterized by conceptual and methodological continuity. This approach is based on the accumulation of past experiences, which are assimilated and reworked rather than completely renewed with each new construction. This process fosters the development of constants, namely recurring principles or elements that manifest themselves through Nervi's design practice.

This approach can create a procedural parallelism with the contemporary practice of upcycling: the recovery of long-span structural components reused in the new building design process (which may require an improvement in their performance, including the repair of any structural portions that have deteriorated over time) leads to the preservation of an idea of space over time.

To conclude, the adoption of "Design for Disassembly" and upcycling practices encourages a series of open questions about the opportunities and frontiers in the field of 20th-century authorial architecture.

First, it represents an opportunity for the preservation and transmission of cultural and intellectual heritage to future generations. It's not just about physically preserving buildings and structural components, but also safeguarding the very essence of the ideas, innovation, and vision that guided their creation. This immaterial dimension is just as precious as the material one and the upcycling of components offers an alternative that enhances both dimensions. Secondly, upcycling constitutes a tangible opportunity for the creation of new local value chains.

Finally, we must consider that with these practices, design begins by engaging with specific building components, this informs both the process and the outcome. Consequently, the possibility of reusing existing concrete structural components inspires surprising and innovative spatial solutions, broadening the panorama of contemporary architecture. This approach not only reduces the environmental impact of the construction industry but also opens new frontiers and design scenarios. ■

BIOGRAPHIES

Alberto Bologna is an architect, PhD, and an Associate Professor in Architectural Design at the Faculty of Architecture – Department of Architecture and Design (DiAP) at the Sapienza University of Rome (Italy). He is the teaching-scientific coordinator of the Second Level Master "PARES" and member of the scientific board of the PhD program in "Architecture and Construction" at Sapienza University of Rome. From 2011 to 2015, he was a post-doc scientist at the EPFL–École Polytechnique Fédérale de Lausanne (Switzerland).

Margherita Maurea is an architect and a PhD candidate in Architectural Design for Urban Environment at the Department of Architecture of the University of Naples Federico II. Graduated with honors from the same University, she is dedicated to academic research and actively contributes to teaching through participation in architectural and urban design workshops. Her research interests address methodological and processual issues within the field of architectural design, particularly focusing on the work of Pier Luigi Nervi.

VILNIUS CONCERT AND SPORTS PALACE – TRANSFORMATION OF THE PRESERVATION APPROACH

AUŠRA ČERNAUSKIENĖ
VILNIUS UNIVERSITY

#08

ABSTRACT

The text examines the dramatic transformation of evaluation and preservation approaches for one of Lithuania's most widely-known concrete heritage icons—Vilnius Concert and Sports Palace. In the last twenty years, the approach has led to a change from a concrete monster to an appreciated heritage object by the public. During these years, different scenarios for the Vilnius Concert and Sports Palace have been considered: demolition, adaptive reuse with extensions, and conservation as a monument. The latter scenario raises more questions than answers, especially considering the global climate crisis and the urgent need for responsible energy use. However, despite the public's and experts' attention and appreciation, the Palace remains abandoned in the city centre.

A multi-layered holistic value analysis, represented in a text, reveals arguments as to why it should be adopted rather than conserved as a monument and left to become a fenced concrete ruin in the middle of the city centre.

1. INTRODUCTION

Many dismissed landmarks of concrete long-span buildings of the 20th century worldwide face functional obsolescence and have become a puzzle for heritage specialists and city governments. On the one hand, the dilemma of preserving buildings is maintaining their authenticity and leaving them as "*distinct signs of modern,*"[1] and on the other – adapting them to the changing needs of modern society and the challenges posed by both the global climate crisis and "*inspiring creativity*."[2] The Vilnius Concert and Sports Palace is one such case in Europe. It is an icon of modernist planning and brutalist aesthetics in Lithuania, which has lost its functional relevance. Besides all that, the Palace faced an extra challenge—dealing with the negative and brutal consequences of the Soviet regime, which complicated its sustainable future all the more so.

The Palace is notable for its hanging cable-suspended roof covering an ample interior space of 60 x 60 metres. It was designed as a part of a newly formed sports complex in the centre of Vilnius as a universal arena of international standards for an ice hockey rink to host 6000 spectators (**Fig. 1**). It was built from 1965 to 1971 in Soviet-occupied Lithuania in the historic part of Vilnius, next to the old town and in front of the medieval Gediminas Castle in the bend of the river Neris. The group of talented architects Eduardas Chlomauskas, Jonas Kriukelis, Zigmantas Liandzbergis, and engineers Henrikas Vytautas Karvelis, Algimantas Katilius, Aleksandras Kamarauskas and Sofija Kovarskaja designed the Palace. The structural solution of the elegantly curved roof – the inverted arch – was recognized as the invention of engineer Karvelis, and the authors were awarded the Prize of Lithuanian SSR in 1973.[3] The Palace was built as a part of the larger cultural-sport complex with Žalgiris Stadium and an Indoor Swimming Pool (both were demolished and replaced by new developments).

Ironically, the Palace never hosted ice hockey. Instead, it hosted essential basketball games in 1987-89, and "*basketball became one of the catalysts for the national revival movement.*"[4] The Palace also hosted the first National Liberation Movement "Sąjūdis" congress in 1988, which was a strong catalyst for Lithuania's restoring independence, achieved in 1990. Additionally, the victims of the independence struggle in 1991 were honoured there.

A more significant concern for preserving the Palace did not occur until the first decade of the 21st century when real demolition threats appeared. Despite its vital contribution to the restoration of independence, the Palace was primarily criticised by the public because of its grey aesthetics and was treated as a concrete monster. Further pressure was applied by developers to replace the Palace with new contemporary buildings. In 2006, due to the threat of demolition, the Vilnius Concert and Sports Palace was listed on the National List of Cultural Heritage. The inscription was determined by heritage experts not only because of its significant architectural and structural solutions but also as a result of its historical value related to events of independence, which played a crucial role in listing the building.

The future or adaptation of the Palace would not be so complicated if it were not for the history of the location where the building stands. The

Palace was built on the old Jewish cemetery dating back to the 16th and 18th centuries. Despite the neglect of the old cemeteries, their location during the construction was hidden from the public, and it shows the strategy of the former Soviet regime to introduce new, massive buildings in or near essential and sensitive historical and religious sites in order to erase memory. The territory of the old Jewish cemetery was included in the national heritage list several years after the Palace in 2008. The difficulty lies in the fact that the Palace, as immovable cultural property, has territorial boundaries with the land under the building, while the protected boundary of the cemetery territory is the delineation of the land on which the Palace stands (**Fig. 2**).

Such demarcation of territories raises many questions and conflicts. If the Palace is not within the territory of the Jewish cemetery, can it be adapted for cultural purposes? How can the territory of the cemetery be marked while maintaining the modernist principle of open public space? How can a vast area in the city centre be arranged so that respect for the Jewish cemetery is maintained, but it does not become a closed and inaccessible public space?

2. APPROACHES TO REVIVE THE PALACE

Three scenarios are commonly used to preserve concrete heritage: *conservation*, *upgrade*, and *adaptive reuse*.[5] The first scenario – *conservation* – is primarily described in recent international documents as a strategy for preserving highly significant concrete buildings recognized internationally and nationally.[6] In the case of conservation, interventions and minor additions are allowed to ensure the proper functioning of the building, and the purpose should be to replicate the original as possible. Suitable methods to keep fair-faced concrete surfaces and structures as authentic as possible are to be employed. The second scenario – *upgrade* or *renovation* – is mainly used to improve engineering systems, usually for residential housing objects or as a temporary solution for public buildings to solve urgent problems. The third one – *adaptive reuse* – is the most widely used scenario suitable for significant concrete objects with an outdated, no longer relevant function, which needs a major transformation to fit a new purpose. It combines conservation and reconstruction approaches to concrete surfaces and structures, prioritizing methods that keep fair-faced concrete surfaces as authentic as possible. The scenario of adaptive reuse *"gained more popularity in Europe than strict conservation, except for the small number of iconic objects*."[7]

Considerations for the preservation of the Palace began as early as 2008 when the Vilnius municipality announced an architectural competition to transform the territory of the Palace and the adjacent Žalgiris Stadium into a multi-purpose centre. The Architectural Studio of Sigitas Kuncevičius won the contest. The reconstruction project of converting the Palace into a Congress Centre with an extension volume was prepared in 2016, preserving all specified valuable attributes.[8] However, the implementation of the reconstruction was stopped by the Jewish community, which claimed that there could be burials under the Palace and that such an entertainment purpose as the congress centre was unsuitable for this historic place.[9]

5. Three scenarios for post-war concrete heritage are analysed in more detail in the article: Aušra Černauskienė, "Preservation Scenarios for Post-War Concrete Architecture: The Case of Lithuania," *Architecture and Urban Planning*, vol.19, no.1 (2023): 217-229. https://doi.org/10.2478/aup-2023-0020

6. Based on recent documents: *Cádiz document* by ICOMOS (2021) and *Conservation Principals for Concrete of Cultural Significance* by GCI (2020)

7. Theodor H. M. Prudon, *Preservation of Modern Architecture* (New Jersey: John Wiley and Sons, 2008), 13.

8. More about the conversion project of the Palace to Congress Centre: https://www.vas.lt/portfolio/items/sporto-rumai/

After several years, the government put forward another use for the Palace—converting it into a Jewish Museum, proposing the Polin Museum in Poland as an example.[10] The Jewish community rejected this idea based on the same argument – that no cultural purpose should be introduced for the building, in order to avoid large gatherings of people for entertainment. To solve the complicated situation, in 2023, an international workgroup of experts was established under the order of the LR prime minister. The experts were asked to find a suitable solution that included respect for the Jewish cemetery and the Palace's contribution to the Lithuanian Liberation Movement. The expert group completed their work this February, and the government will announce the final resolution soon. According to the latest expert reports in the media, only minimal adoption of premises for the Palace has been considered for a memorial purpose.[11] A memorial will be dedicated to Jewish historical memory and the struggles of the Lithuania Liberation Movement "Sąjūdis." In such a way, historical justice will be restored.

It must be noted that the most realistic scenario now is to conserve the giant concrete building as a monument, with the ancient Jewish cemetery being physically fenced off. The proposed revival of the Palace involves *conservation without use*. This is seen as a political action to acknowledge and take responsibility for past mistakes made by the Soviets in Lithuania, a democratic country. The primary focus is on preserving historical values and restoring historical justice. Other important features of the Palace, such as its iconic modern design, innovative roof construction, or rare brutalist aesthetics, are considered less significant. Moreover, the public was not consulted or included during the expert work, which contradicts the principles of holistic evaluation of heritage objects.

It appears that the appropriate time for adaptive reuse of the Palace has already passed, and now it could be treated as a concrete ruin in the middle of the city telling its own complicated story. A new architectural competition will be held to meet the new requirements established by the working group and approved by the government of the Republic of Lithuania.

Considering the context of Baltic states, the Palace could be compared with LinnaHall in Tallinn, Estonia (1975-1980, arch. Raine Karp, Riina Altmäe). LinnaHall is also a listed object, built for the Olympic games, but it is still next to an old town and is ill-suited to new life.

3. HOLISTIC EVALUATION OF THE PALACE

Before selecting the appropriate preservation plan, it is essential to conduct a multi-layered assessment of value, identify unmet contemporary social and technical needs, and evaluate the physical condition—this overall process could be considered a holistic evaluation.

Value is a constantly changing dimension describing an object's relationship with a broader context, "*values and other forms of meaning are produced out of the interaction of artifacts and their contexts, not from the artefact itself*."[12] It means that various social and economic relations, exchanges, and acts of "local agents" circulate in or close to the heritage

itself, creating new values over time. In addition, cultural objects, especially large-scale cultural ones, shape the identity of the cities, contribute to the economic value of the surrounding environment, and form part of "*territorial capital*."[13] Therefore, evaluating heritage objects is a multi-layered process in which expert and non-expert evaluation[14] is essential.

The author created the 5+5 evaluation matrix (**Fig. 3**) to examine the objects of concrete heritage in Lithuania holistically. In the case of Vilnius Concerts and Sports Palace, it is used to reveal why the Palace should be repurposed for cultural purposes concerning all layers of history and culture rather than left as a fenced concrete ruin, conserved as a monument.

The matrix comprises five aspects of cultural value: urban, artistic-aesthetic, social-anthropological, historical, and technological.[15] In addition to aspects of value, five factors have been identified that either strengthen or weaken the object's cultural value. These factors are: TT comparative analysis (comparing buildings of the same technology and typology), authenticity and integrity, physical condition and possibilities of reuse, sustainability and economy, and non-expert evaluation.

Certain matrix elements are widely used in the evaluation of heritage sites. Among these, we can single out historical, aesthetic, and technological aspects and strengthen factors such as authenticity, integrity, and physical condition. They are commonly used to describe the valuable features of heritage objects in Lithuania. Other aspects such as urban and social value aspects and factors of sustainability, economy, and non-expert evaluation, are used less frequently and affect the incomplete realisation of potential values.

While holistically analysing the Palace's values, in addition to historical, aesthetic, and technological, an urban value revealed itself that contributes significantly to the identity of the capital, Vilnius, and the district of Šnipiškės. It raised the value of the surrounding territory and brought about new development. Moreover, the open public space surrounding the Palace, created by terracing the relief, is a vital and valuable attribute of modernist planning, which could be easily destroyed by enclosing the territory of the Jewish cemetery. This is also closely related to social value – a public place important for local communication.

Evaluation of sustainability and economic factors are also missing, which are essential in choosing a suitable preservation scenario. Heritage objects work well when used and visited, arouse curiosity, express past innovations, are educationally engaging, and reveal various layers of history and renewal methodologies. In addition, the Palace is a large concrete building spanning 14,750 square meters featuring raw concrete surfaces that will require heating, ventilation, constant maintenance, and monitoring.

Finally, it is important to include a non-expert evaluation as part of a more comprehensive evaluation process. In recent decades, the evaluation of the Palace has dramatically changed from that of public neglect to appreciation in Lithuania. The Palace has been recognised as an essential part of modern heritage, as evidenced by the Open House Vilnius festival, during which the Palace has attracted many curious visitors for several years

13. Heritage as an important part of "territorial capital" was analysed in the recent book: Mariusz Sokołowicz, Aleksandra Nowakowska, and Blazej Ciarkowski, *The Ambiguous Legacy of Socialist Modernist Architecture in Central and Eastern Europe* (Abingdon, Oxon: Routledge, 2023), Chapter 2 and 3.

14. Expert and non-expert evaluation of the heritage is emphasized by Rodney Harrison (2013) and Janet Stephenson (2008).

15. Five aspects of value were selected after examining a wide range of theoretical works (Riegel, Alois (1902), Lipe, William (1984), Mason, Randall (2002), Keene, Edward (2005) and others) and evaluation criteria applied by international heritage institutions UNESCO, ICOMOS, DOCOMOMO.

Figure 3. Matrix of holistic evaluation © Aušra Černauskienė, 2024

Figure 4. Vilnius Concert and Sports Palace during the Open House Festival © Norbert Tukaj, 2019

(**Fig.4**). The significance of the building is also proven by international databases such as "100 from the 20th" or "SOS Brutalism," which included the Palace as an iconic example of concrete heritage objects in Lithuania.

However, despite the public's and experts' attention and appreciation, the Palace remains abandoned in the city centre, awaiting a political decision and new architectural competition. Meanwhile, raw concrete surfaces rapidly deteriorate because of lack of maintenance, graffiti, weathering, and biological coating.

4. CONCLUSIONS

Over the past few years, the approach to preserving the Vilnius Concert and Sports Palace has changed dramatically from considering adaptive reuse with additions to now conserving it as a monument, without using the building for even cultural purposes. From a holistic assessment perspective, the chosen scenario does seem the most appropriate for a building of this size and brutalist aesthetic. The Palace holds significant value in a number of aspects, and deciding on its future preservation should not be a mere political decision or a model based on expert assessment and historical value.

The Palace, as an icon of modernism and brutalism, is worth being used and adapted for a cultural purpose while maintaining respect for the Jewish cemetery and honouring the Lithuanian Liberation Movement. Inspiring creativity and open dialogue with the public is urgently required to prevent the Palace from becoming just a fenced-in concrete sculpture that will require high maintenance costs. All value aspects and factors such as sustainability, the economy, and the public's opinion must be considered when formulating new competition conditions for the Palace. ■

BIOGRAPHY

Aušra Černauskienė is a post-doc researcher at Vilnius University, Faculty of History, Lithuania. She holds a PhD in Humanities (2021). Her research is focused on the preservation of concrete-based architecture of the 20th century.Since 2009, she has been a certified practising architect and co-author of public and residential buildings, projects, and workshops. She currently works as a freelance architect and is a member of the Architect's Chamber of Lithuania and ICOMOS Lithuania.

METHODOLOGICAL APPROACHES THROUGH THE USE OF ADVANCED INFORMATION SYSTEMS (BIM-GIS AND CDE) FOR THE MANAGEMENT AND VALORISATION OF 20TH CENTURY INDUSTRIAL HERITAGE

ANTONIO MARIA NESE
DEPARTMENT OF ARCHITECTURE,
UNIVERSITY "G. D'ANNUNZIO" CH-PE, ITALY

ABSTRACT

The industrial heritage of the 20th century represents a significant fragment of architecture that requires fundamental preservation. The rehabilitation of industrial buildings not only offers an opportunity to conserve historical memory, but also provides an occasion for the functional rehabilitation of such structures.

In terms of environmental and economic impact, the redevelopment of industrial buildings emerges as a sustainable solution that avoids the demolition and construction of new structures. This process can be identified as a form of urban regeneration.

The aim of this research is to propose a comprehensive and integrated methodological approach for the management and enhancement of the rich industrial heritage of the 20th century. This approach is founded on the utilization of sophisticated information systems, including interoperable digital models obtained through the integration of BIM- GIS (Building Information Modeling Geographical Information System) and CDE (Common Data Environment) implementation.

The primary objective is to develop effective tools and strategies to ensure the continuity and preservation of these valuable historic sites. To that end, the creation of a dedicated platform, linked to an open- source interactive map, is proposed. Such platform would enable efficient and accessible management of all data and information relevant to the sites uploaded within it.

Through this innovative platform, it will be possible to store and share detailed data on industrial sites, as well as to facilitate the collaboration and participation of stakeholders in the planning and management of conservation and enhancement activities.

To develop this methodology, three significant case studies were considered in which the adaptive reuse approach has been applied: the Ex Manifattura Tabacchi in Florence (Former Tobacco Factory), the Ex Magazzini-Generali in Verona (Former General Warehouses) and the Ricevitrice Nord AEM in Milan (North Receiver AEM).

1. INTRODUCTION

The enhancement of the industrial heritage is of considerable importance and is embraced by a broad vision aimed at the preservation of artifacts that hold intrinsic cultural and architectural significance, which has marked and continues to characterize our territories from the earliest stages of the industrialization era.

The adaptive reuse of existing buildings, as opposed to demolition, is a method aimed at reducing construction costs and accelerating construction time. Such practice provides an opportunity to improve the energy efficiency of existing structures, while ensuring their long-term sustainability, thus preserving the important architectural heritage. Furthermore, adaptive reuse allows buildings to be reimplemented with new features, thereby contributing to the revitalization of surrounding areas, combating urban sprawl and the resulting land consumption.

The industrial heritage of the 20th century represents an invaluable cultural legacy, serving as evidence of a bygone era that shaped both society and its surrounding environment. Nevertheless, the preservation and enhancement of such assets face challenges of a complex nature, in part due to their lack of digitization.

The synergistic integration of advanced technologies, such as Building Information Modeling (BIM) and Geographic Information System (GIS), along with the use of Common Data Environment (CDE) and other innovative systems, assumes a pivotal role in the digital transformation of architectural heritage, which is still lagging behind on the digitization front despite the interest aroused by the scientific community.

The present paper, through three case studies characterised by adaptive reuse approaches, proposes a methodological process structured in a replicable manner, divided into several phases, aimed at digitizing such heritage. The use of integrated digital twins enables an accurate management of recovery and enhancement activities.

Furthermore, sophisticated technologies such as BIM-GIS and CDE facilitate proactive protection, which focuses on preventing safety issues and mitigating risks before they occur. Digitization through such systems currently represents the most effective approach for the management and maintenance control of the building throughout its life cycle.

2. CASE STUDIES

2.1. THE EX MANIFATTURA TABACCHI IN FLORENCE (FORMER TOBACCO FACTORY)

The practice of tobacco use in Tuscany can be traced back to the second half of the 18th century. However, it was not until the 19th century that it became a common practice in daily life. This mass diffusion rapidly gave rise to the formation of the "Manifatture". In the early 1930s, a substantial construction project began, with the construction of the Nuova Manifattura Tabacchi (New Tobacco Factory), which assumed a pivotal role in the economy, the urban planning, and the socio-economic

life of Florence. The official inauguration occurred in November 1940 (Manifattura Tabacchi, 2024).

The architectural design is the work of Pier Luigi Nervi, associated with the firm Nervi & Nebbiosi. The architectural layout of the new facility adheres to precise distribution principles: along the urban frontage of Via delle Cascine, we find the executive offices and the Puccini Theater; along the rear boundary of the lot, the warehouses and the workshop are located; in the center of the complex there are the production areas and the general services. The various functional units are connected by a network of pedestrian walkways and driveways within the area; outside the lot, the railway provides the service infrastructure for the factory (Manifattura Tabacchi, 2024).

After more than 70 years of operation, the complex was closed in 2001. In 2016, an ambitious project was initiated with the goal of transforming it into a new cultural hub, featuring the vibrant energy of fashion, art and design. This project envisions a multifaceted mix of functions, in which the original and new buildings house schools, ateliers, workshops, offices, co-working spaces, lofts, a hotel, a student residence and a brewery. The initial plan, later developed by SANAA and Studio Mumbai, involves a group of top professionals: Q-bic for technical consulting, landscape architect Antonio Perazzi for green spaces, Piuarch Studio for new construction and Patricia Urquiola for interior design of 45 residences. The project's approach to minimizing demolition allows for the reinterpretation of the original structures in a sustainable manner, making them more efficient through the use of geothermal systems and active management of water resources; the planting of over 1,000 trees is accompanied by a roof garden, which is situated above the building (Cantoni, 2023).

2.2. THE EX MAGAZZINI GENERALI IN VERONA (FORMER GENERAL WAREHOUSES)

The idea of creating central warehouses in Verona originated in the latter decades of the 19th century. The city needed a complex of centralized facilities for the collection, storage and distribution of fruit, vegetables, and grain products. The project, which was realized during the 20th century, resulted in the construction of one of the most sophisticated facilities of its kind in all of Europe. It served as a symbol of the policy of modernizing industry and infrastructure through a vast program of public works.

Several buildings were constructed between 1925 and 1938 with the aim of creating central facilities for the collection, storage, and distribution of fruit, vegetables, and grain products. One of the most important buildings is the Stazione Frigorifera (Refrigeration Station), designed by engineer Pio Beccherle. This circular building echoes the structure of the earlier Forte Clam and was inspired by the Halle au Blè building in Les Halles in Paris (Curtis, 1999).

The Stazione Frigorifera designed by Beccherle features a circular floor plan with a large domed hall in the center that represents a technological innovation that makes it the most important in Europe (Albertini, Colato, Segala, 1996-97). The building's external appearance is striking due to its

considerable size and the large 30-meter-high dome that towers above the structure (Pisani, 2011).

Abandoned in the 1980s due to the relocation of the Magazzini Generali to another area, the building is currently undergoing a process of revitalization, with a new vision and philosophy guiding the project, equipping the complex with the latest technological standards while preserving valuable architectural elements. The intention is to create a hub of innovation, work, culture, art and gastronomy. A true Commercial District, which already houses several buildings.

2.3. THE RICEVITRICE NORD AEM (NORTH RECEIVER AEM, MUNICIPAL ELECTRIC COMPANY)

The Ricevitrice Nord, inaugurated on December 8, 1932, by then Prince Umberto II of Savoy, with its composite architecture slightly influenced by the Deco style, has long been a landmark in the working-class Precotto area. Constructed to serve as an electric receiver in the northern area of the city in response to the increased power output of the Valtellina hydroelectric systems, the "Ricevitrice" continues to this day to fulfill its original task, supplying power to a large portion of the Milan metropolitan area (Fondazione AEM, 2024).

The Ricevitrice Nord, currently owned by the a2a company, continues to fulfill its primary function in a manner that is naturally adaptable to contemporary needs. The renovations did not entail significant alterations, particularly with regard to the fundamental structure of the building.

The central electrical devices in the energy transformation process are transformers. The complex includes the Sala Operativa (Operations Room), which provides an opportunity to observe how new telecommunications infrastructure and modern protection and control system technologies are gradually improving the power grid in and around the city of Milan.

Such technological advances are undeniably transforming power distribution networks, making them increasingly advanced and intelligent.

3. BIM-GIS, CDE AND THE APPLIED METHODOLOGY

At a time when technological advancement is transforming many sectors, the need to manage and digitize the building stock arises. The following section proposes a strategy for addressing these issues.

The BIM approach, when combined with GIS, provides an appropriate tool to meet the challenge of digitization. In fact, the integration of BIM with GIS provides an opportunity to optimize the heritage management process, enhancing its efficiency, cost-effectiveness, and sustainability. The use of integrated digital models enables accurate synchronization of this process. In short, BIM provides a wide range of detailed information about the work, both in terms of geometry and semantics. However, it does not include information about the surrounding environment (Rafiee A. *et al*., 2014). In contrast, GIS uses the functional and physical relationships of the surrounding environment on a larger scale, to conduct spatial analysis. However, it has a significant shortcoming: the lack of a comprehensive and detailed digital archive regarding building information (Amirebrahimi S. *et al*., 2015).

From an information perspective, it is precisely this complementarity between BIM and GIS that makes their integration an advantageous combination to achieve significant results on multiple fronts.

The purpose of this research is to propose innovative solutions, through advanced technological systems, to facilitate the digitization of architectural heritage processes. This goal led to the construction of a replicable methodology, organized in phases.

The research focus is the development of a comprehensive and integrated methodological approach for the management and enhancement of the 20th century industrial heritage. This approach is founded on the utilization of sophisticated information systems, including interoperable digital models obtained through the integration of BIM-GIS and CDE implementation.

The primary objective is to develop effective tools and strategies to ensure the continuity and preservation of these valuable historic sites. To that end, the creation of a dedicated platform, integrated with an open-source interactive map, is proposed in order to facilitate the efficient management and the access to all relevant data and information related to the sites.

Through this innovative platform, it will be possible to store and share detailed data on industrial sites, as well as to facilitate the collaboration and participation of stakeholders in the planning and management of conservation and enhancement activities. As a first step, a survey was conducted to identify buildings that could serve as case studies within the 20th century industrial heritage in Italy. The choices were the Ex Manifattura Tabacchi in Florence (Former Tobacco Factory), the Ex Magazzini-Generali in Verona (Former General Warehouses) and the Ricevitrice Nord AEM in Milan (North Receiver AEM).

Subsequently, a variety of documentary materials pertaining to the selected building underwent a process of retrieval and research.

Following the collection of the documentary materials, the cataloguing sheets were organized. These sheets contain the main information regarding location, classification, the artifacts that comprise the site, historical annotations and other general details.

The collected data were saved in a desktop folder and then stored in the Common Data Environment (CDE) platform.

Subsequently, a fast digital survey of the buildings was conducted using the photogrammetry technique. The frames were obtained from the Google Earth Pro virtual tour by obtaining ten frames for each second of the tour.

The acquired frames were imported into the Agisoft Metashape software, whereupon they were processed in order to obtain a point cloud of the detected object, followed by the generation of meshes and a textured model **(Fig. 1)**.

Once the models had been developed, they were exported in the .dxf interchange format to be opened within Autodesk's BIM software, Revit **(Fig. 2)**.

The obtained files were opened and georeferenced within the Autodesk Revit software, serving as the basis for the construction of the parametric model in BIM into which, subsequently, building information data were

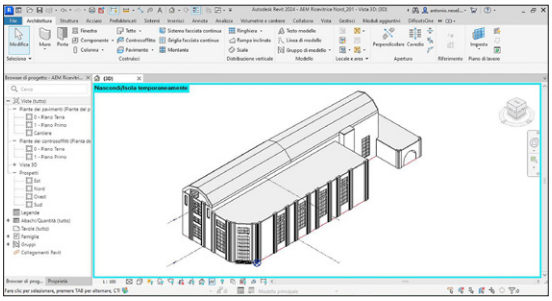

Figure 2. Ricevitrice Nord AEM (Nord AEM receiver), development of BIM models in Autodesk Revit (elaboration A. M. Nese 2024).

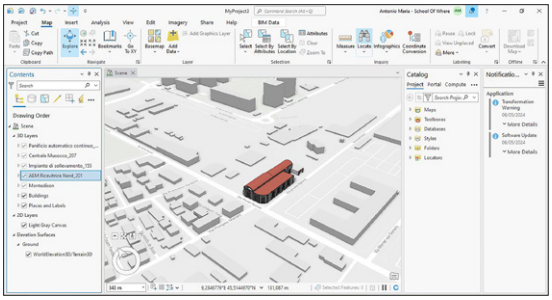

Figure 3. Ricevitrice Nord AEM (Nord AEM receiver), integration of BIM models on ArcGIS software (elaboration A. M. Nese 2024).

incorporated. The realized models were exported in .ifc (neutral and open file format used for BIM).

Once completed, the BIM models were uploaded into ESRI's ArcGIS Pro software. This step allows the combination of BIM and GIS territorial data, input and visualization, analysis and management in its real-world context. Such integration is increasingly being investigated by the scientific community as well as by professionals, since, as previously stated, information management can be achieved both from a territorial perspective (GIS) and in the detail of individual building elements (BIM), with obvious advantages **(Fig. 3)**.

All materials, both retrieved and produced, were archived on the CBOX (CDE) platform, owned by Anafyo Sagl. CBOX is a digital environment, suitable for the collaboration among the various figures involved in a project, supported by cloud technology, which allows the archiving, sharing, and visualization of documents and BIM models. Additionally, the platform offers a degree of configurational flexibility, capable of adaptation to a variety of distinct operational contexts.

All materials generated throughout the various stages of the process were uploaded within CBOX through specifically organized folders and subfolders. Such materials encompass all data pertaining to the building of any kind.

Finally, through ArcGIS Pro, a web map is created that allows the online publication of BIM models positioned in their actual context. It also gives the possibility of downloading the building's cataloguing sheet and opening the link for access to the CBOX platform.

4. CONCLUSIONS

The study in question attempts to demonstrate the considerable advantages of integrating the various technological systems employed, with a particular focus on heritage management and governance. However, it is important to acknowledge that there is still room for improvement, particularly in relation to the more synergistic integration between BIM and GIS, which assumes an increasingly crucial role in land planning and management.

The selected methodological proposal aims to encourage the digitization of architectural heritage - in this case 20th-century industrial heritage - which has been experiencing delays. This approach also encourages a broader reflection on the importance of preserving and enhancing these assets, which have assumed historical and cultural value. Such approach is essential for addressing a number of challenges related to the preservation and the sustainable enjoyment of these resources, thus setting the stage for a more conscious and respectful future for our common heritage. ■

BIOGRAPHY

Antonio Maria Nese (Salerno 1991), is currently a PhD candidate for the 37th cycle at the University of Pescara. His research focuses on the integration of BIM-oriented processes with GIS and Common Data Environment systems for the management of architectural heritage, with a deep analysis on industrial heritage. He graduated from University of Chieti-Pescara in architectural restoration with the thesis work "Conservare un tabacchificio dismesso" in 2020. After graduating, he embarked on his professional career at an architectural firm, where he had the opportunity to follow international projects. In order to further explore the research in the industry, he spent six months at Anafyo Sagl based in Lugano, Switzerland.

RE-INHABITING THE MODERN FACTORY: THE FORMER MILK PLANT BY LUIGI COSENZA

#08

FRANCESCO IULIANO
UNIVERSITY OF NAPLES "FEDERICO II"

LORENZO RENZULLO
UNIVERSITY OF NAPLES "FEDERICO II"

ABSTRACT

Between Caserta and Naples, there is a vast architectural sampler generated by high quality experimentation: from Mangiarotti's Siag factory (1962) to the Ex-Olivetti factory in Marcianise (1972), which Zanuso carried on with Eduardo Vittoria, and the Kodak factory in Marcianise (1974), which saw Gianluigi Ghò flank Aldo Favini. For such designers, industrial architecture became the ideal place in which to codify a rich vocabulary of structural forms, capable of ensuring distributive flexibility and being programmed for subsequent extensions. Today, this sample of factory buildings, constitutes a heritage almost totally in a state of abandonment. The aim of the research is to rethink the role of work and production spaces in the contemporary city with reference to the case of Luigi Cosenza's former milk plant in Scampia (NA), now decommissioned. The building has a cross-shaped layout and is articulated in a series of bodies with reinforced concrete pillars and beams cast in situ. The purpose of this study is to broadening the debate on the possible strategies of protection and valorization of the Modern Movement production. Through an historical and archival research of the original project, both the reasons for the disuse of the complex and the specific characteristics of the architectural, technological and functional elements will be reconstructed. As regards the building envelopes, in order to balance conservation actions and thermal and energy adaptation actions, a multi-criteria methodology has been adopted to select the most appropriate hypothesis of intervention. The research looks to the "incremental reuse "approach as a possible solution of intervention in order to return, over time, available surface area to the community, and defining an incremental use of spaces in programmatic and temporal terms, elaborating experimental models of continuity and updating of the works of the Modern.

1. INTRODUCTION: RETHINKING MODERN INDUSTRIAL HERITAGE

The research on 20th-century architecture has become increasingly central in the field of research, as evidenced by numerous programmes for the documentation, conservation and enhancement of Modern heritage. Although many authors studies the theme of industrial architecture, it is necessary to focus on the disused heritage which offers a possibility of renewal based on what already exists. When Giuseppe Pagano into the pages of *Casabella 1942* claimed for the Industrial heritage the significant of a true expression of life and manifestation of the spirit, he intended to recognise the place of production with the same dignity as any urban place[1]. In this context, issues related to the requalification and reuse of industrial buildings also emerge, with the aim of responding to future usage demands and contemporary regulatory, functional, structural, and environmental contingencies. In fact, the main characteristics of these building types - part of that "category of the existing"[2]- today show the main problems in terms of degradation, energy-technological performance, and requalification strategies. Luigi Cosenza's position is significant because his rationalist approach to architectural design is balanced by a "compositional freedom of spaces inherent in spontaneous architecture"[3], warning of the danger of overvaluing preconceived compositional schemes detached from real needs[4]. In 1960 century in Italy, architects and engineers designed large concrete works in which the large size of the space led to the spread of the typical single-storey pavilion with high internal seriality and a wide structural grid. However, the problems associated with the use of concrete building systems led to the emergence of possible intervention approaches. Therefore, alongside more durable and suitable solutions in terms of material characteristics and design of concrete components, in recent years adaptive practices of Industrial authorial architectures, have emerged in Europe, accompanied by original housing policy programmes.

2. DIUSED HERITAGE AND URBAN PLANNING PROCEDURES: THE MILK PLANT BY LUIGI COSENZA (1968)

Despite the technological progress in the industrial sector arrived lately in Campania Region, we can recognise the presence of some paradigmatic cases of Modern industrial architecture by Luigi Cosenza, which have progressively been affected by abandonment; for example, the "Mercato Ittico" and the *Olivetti Factory* project[5]. In the northern area of Naples, the Scampia district, embodies the term "suburban", no longer with a geographical connotation, but as a place of monofunctionality, between dormitory industrial neighbourhood. With the *Law 167-1962*, the urban layout of the district was characterised by the presence of equipped axes and heterogeneous building types, united only by their large scale and the massive amounts of undefined open space that divided them[6]. After the *Piano delle Periferie* of the 1980s, several requalification and urban reclamation plans followed: from the 1995 *Programma di Riqualificazione Urbana del quartiere Scampia*, which rehabilitated numerous abandoned spaces and buildings, to the new *Restart Scampia* project in 2019. Following the

progressive disregard by the administrations, Scampia today registers a lack of a whole series of services. Luigi Cosenza's former Regional milk plant (1968) (**Fig.1**), stands at the opposite end of the well-known *Olivetti Factory* in Pozzuoli, progressively invested by a slow process of abandonment and subsequent decommissioning. Given the lack of scientific publications on this building, an attempt has been made to reconstruct the history of this building through archival documentations. The reasons for the divestment are related to failure revisions of the urban road system, in derogation of the architect's original project indications. From the urban planning project, in the *Provvedimenti di attuazione, Art. 132, ambito n.7, scheda 60*, a building capacity of about 1,560 rooms (450 dwellings) was provided in addition to the 190 rooms (50 dwellings) indicated by the urban regulations. The *Relazione tecnica* of 1974, states that access to the industrial complex was to be from the external ring road. Subsequently, in the *Relazione generale* of 1985, was reported that the lack of any information on the presence of the new Regional Milk factory - already constructed in its structure and therefore with a completely defined internal mobility system - led the Municipality of Naples to build an elevated road, independently of the needs of the Milk Centre. Subsequently, architects Mario Rispoli and Giancarlo Cosenza questioned the criteria, placements, and existing constraints, because they lacked a general unified project, without seeing any follow-up.

2.1. ANATOMY OF AN ARCHITECTURE: TYPOLOGY, TECHNOLOGICAL AND CONSTRUCTION SYSTEM

Luigi Cosenza's works "demonstrate that it is not possible to adopt universal solutions in every case, but that the surroundings of the building play a very precise defining role"[7]. The cross-shaped plan of the former Milk Centre is articulated in a series of factory buildings between 4.50 and 7.50 metres high, characterised by the use of reinforced concrete frames with cast-in-place columns and beams, using formwork, with spans covering up to 18.00 meters. The structural pillars in a first version were circular in cross-section and equipped with a central steel pipe for the drainage of rainwater from the roofs, while in the final version, they were redesigned with a rectangular cross-section covered with an angled sheet metal to allow the passage of any electrical conduits from the floor to the roof beams. This type of industry required specific installations for the milk production chain, its thermal treatment, storage, and transfer to silos. From the gatehouse it was possible to access the common services, the administrative offices, and to a courtyard from which one could reach the laboratory floor, the conference room and access to the roof gardens. The flooring varied according to the functional compartment and the internal finishes are: coloured by quartz plaster for the office/direction area; exposed glazed bricks for longitudinal walls between pillars for processing rooms; exposed concrete with *Sqndtex* type protection for pillars/overhanging intrados; smooth cement plaster for social service storage areas walls. The external finishes are made of exposed concrete, light red facing brick for the back walls and blue litho-ceramic brick cladding

for the ends of the canopy. The window frames are mainly in aluminium of *Fenzi type* with opening sashes, whose thermal transmittance value (U=5.70 W/m^{2}K) does not satisfy the current standards. Finally, the use of external sunshades of *Huinter Douglas* type for the canopies and façades was foreseen and proportionate to the individual spans and differently inclined according to the needs of each specific façade. Therefore, after a careful analysis of the original project and technological elements, a thermal investigation of the building envelope was conducted to determine the actual performances. The recorder current thermal performance of the opaque envelope, with reference to the thermal transmittance value U=1.33 W/m^{2}K, does not comply with the norm restrictions. To preserve the original characteristics of the building, functionality, economy, and aesthetics of the elements, a multi-criteria comparison was carried out to select the preferable intervention hypothesis: integral preservation of the external envelopes, internal insulation, replacement of windows, and addition of external horizontal louvre sunshades in accordance to a preliminary version of the project as found in Luigi Cosenza's archival documentation (**Fig.2**). With these measures, the new thermal transmittance value (U=0.24 W/m^{2}K) complies with the current regulations, which admit the maximum value of U= 0.30 W/m^{2}K.

3. REUSE STRATEGIES FOR MODERN INDUSTRIAL HERITAGE: BETWEEN CONSERVATION AND ENHANCEMENT

The spread of disused author architectures calls for a reflection on the practices of design as a process of modification of the existing, aimed at revitalizing a latent and forgotten heritage, which is, nevertheless, a valuable resource for the community. When author architectures are also industrial architectures, the problem becomes more complicated: born out of the architects' desire to experiment with the tectonic and expressive potential of the factory, they housed in their spaces functions of a productive nature, sometimes even specialized, which seem nowadays anachronistic in the now changed urban context. As a result, the rules guiding interventions on works of a historic nature cannot be employed on this type of material: restoration, as well as the rehabilitation of the state prior to abandonment, are not enough, it is necessary to reflect on the role that the building can play in contemporary times. Starting from the consideration that "The vitality of an architecture is a product of heterogeneous factors, and the effectiveness of the performance of the function for which a building is intended is undoubtedly a foundational condition for its survival"[8] adaptive reuse represents a possible solution, which is understood here as " The process of reusing an obsolete and derelict building by changing its function and maximizing the reuse and retention of existing materials and structures"[9]. Accommodating new uses within the abandoned building allows it to redefine its role and extend its lifespan. Consequently, in this case, it is necessary to reflect on the "disruption of the coherence between their original function and the figurative system related to it"[10], but not only that. To the question of semantic reconfiguration is added the purely spatial one: how to update the spaces that had been determined by

the original function so that they adapt to the new intended use? The former Luigi Cosenza milk plant, because of its size and structure, can be configured as an 'open' building, not locked into a single form but at the service of program flexibility and diverse uses. In the field of industrial heritage intervention, different strategies have emerged over time: on the one hand, some design approaches adopt what is called a 'wrapping strategy', covering the building with new functional layers, inside and outside; this solution might involve structural analysis and upgrade, energy retrofit and new aesthetic and formal connotation. Some other approaches opt for an 'inside strategy', including new lightweight structures and autonomous/self-supporting functional modules within the existing space. Finally, some solutions, pursuing the higher level of transformability and design experimentation, implement a 'naked strategy', with the removal of all the complementary system, as much as allowed by the building, and the conservation of the bare structure of the building[11]. The project seeks to combine the first two strategies by focusing in the relationship between the reinforced concrete wide span bays, which cover the now empty large ex-industrial rooms, and a series of volumes of various sizes that are configured as containers of new functions available to future users (**Fig.3**). The new volumes are made with dry prefabricated solutions, which can ensure fast construction at a lower cost, as well as allow the reversibility of the intervention. The use of infill makes it possible to improve the thermal and acoustic insulation of only a small part of the building and to keep the main structure in its original state, ensuring its preservation. This choice is due to the need to consider the limited budget that renovation operations of objects like this one have at their disposal. In addition to retrofitting, the budget will also have to cover the costs of restoration work and maintenance of the building over time. Due to the large size of the industrial structure, the most economically viable option is the subsequent occupation and transformation of the space: adaptive reuse, consequently, takes on an incremental dimension in this case, both temporally and spatially. The chosen functional program seeks to reinterpret the building's past, as a place of work, updating it according to new needs: the use of empty spaces to settle start-ups and production workshops, including artisanal ones, would improve the local economy, especially for young entrepreneurs, and provide a source of income to finance the transformation of the other spaces intended for the community. Within the former plant it is possible, subsequently, to place exhibition spaces, educational laboratories, auditoriums and multipurpose areas to provide the neighborhood with those public facilities it lacks. Finally, the wing of the building originally dedicated to administration and offices can be converted into temporary housing that offers an initial response to the area's housing emergency. Incremental reuse[12] is also an interesting strategy because of its social implications: given the prolongation in time of the transformations, it is possible to initiate workshops and discussion activities with the local community, so as to ensure participation in the design activities and test the effectiveness of some design choices in the initial stages of operation. Ultimately, the project aims to make

the building radically public, not only in the interpretation of the program but also and especially in its spatial design. The architectural interventions also combine with this goal the desire to maintain the extraordinary spatial qualities already existing, the atmosphere and tone conferred by the materials, proportions, lights, and strong industrial character.

4. CONCLUSIONS

In the context of intervention on disused Modern heritage, the importance of the author and the notoriety of the project exercise a cultural pressure that has paralyzed any attempt to react to the contemporary condition of decay. The result is a stasis that concretely ends up aggravating the building's condition. If we then refer to the specific case of industrial architecture, we add a consistency that is often oversized and out of scale with respect to the conditions of the context. Conceived as pieces of the city, these industrial heritages are in a completely unproductive condition that clashes with the vitality of the immediately adjacent areas. There are two reactions to the current state of these architectures attitudes of rejection that consider these artifacts as abandoned waste that needs to be demolished, and some attentions of the authorities in charge of protection and preservation, who recognize in

these works the trace of the work of an important author and the testimony of a crucial season of Italian architecture. For this category of artifacts, the established practice of recovery, to its original condition, shows all its limitations: we are talking about works that have ceased to play the role they had in the past or even cases in which they have never been in function. The possibilities for a change in the design approach are due to the ambiguity of such materials, placed on the borderline between the monumental and the ordinary heritage, and difficult to be ascribed to a specific field of action. The first step is to consider the disused building as a work available to the superimposition of new uses: the building is no longer a fixed, defined and concluded object, but rather becomes a device, a process in the making that reveals the intelligence of the strategies that guarantee its survival. In this context, author's industrial architecture represents a field in which deeper reflection is needed: articulated in large vacant spaces and now devoid of their original function, they perfectly offer themselves to transformation operations. Actual transformability is, however, constrained by many issues related to typological and technological characteristics, such as the scale of the building and an essential and bare construction system, realized with elementary systems and simple technologies (inspired by economic criteria). Large spans and unobstructed interior space-the absence of pillars or other structural elements are the most prominent features of this type of building while, in most cases, the building envelope rarely presents elements of interest and characterization. Their reuse often introduces alterations and experimentation by which the cultural values of the industrial heritage could be preserved and promoted through the preservation of the memory of the industrial past, but the architectural features and values could be lost. The preservation of the structure ensures the transmission of precisely those values that architects like Luigi Cosenza have concretized with their works where "the ornament is embedded in the process of construction and growth of the building and emerges from the material of which the building is made. It is 'constructed decoration' rather than 'decorated construction' as in the definition of architecture by Auguste Perret"[13]. In order to preserve them, it is necessary to reuse them and adapt those concrete structures that are now empty and without purpose to contemporary times, admitting a certain degree of modification: adaptive reuse combined with an incremental logic, and filtered through the lens of preservation represents the tool available to contemporary architects that is most appropriate to safeguard this at-risk heritage and re-inhabit it. ■

ABSTRACT

The 1950s represented a historical moment of maximum fervor for research on reinforced concrete, which began to assume no longer only a structural value but was reinterpreted in its aesthetic dimension. Although reinforced concrete is the undisputed protagonist of these plastic architectures, it is a material that can be considered "fragile" with respect to the issues of durability and permanence over time as it imposes a limited life cycle on the artifact to be preserved and protected. Two buildings are proposed: the Marxer by Galardi and the Marchiondi Spagliardi by Viganò, currently disused, which need to be recovered in order to ensure their new life. The Marxer Institute is a Brutalist building designed in 1962 in Laranzè (Turin). The complex is dedicated to pharmaceutical research and it is an expression of the plasticity and versatility of reinforced concrete, which is declined in different forms to fulfill the proposed objectives. The Marchiondi Spagliardi Institute, built in Baggio (Milan), is an inclusive building designed for the community, a place charged with historical architectural and engineering values proper to the second half of the twentieth century. The building was designed in the 1950s to accommodate children with difficulties and consists of a dormitory for students, a volume for teachers and a school center. Through a comparative methodology, we analyze the two buildings in which the poetics of reinforced concrete is made explicit through some common elements: the relationship with the urban and the public space, the relationship between the interior and the exterior, the architectural space as one, the great light, the filter-facade, the exposed concrete, the double height and the attention to structural details. The two buildings can thus, mutually, on different themes, represent illustrative tools of a regeneration process that focuses on the design of the existing.

Post-World War II brutalist architecture in reinforced concrete pioneered a series of experimental interventions where the structure served as a model of architectural design that often met the functional requirements of buildings due to its total flexibility. Architects engaged with the material as a design tool: the structure evolved from "load-bearing to supported"[1], with light frames freeing architecture from the superfluous, giving the structure an aesthetic dimension. However, the modern heritage exhibits high fragility due to both technological and structural aspects as well as cultural ones. Reinforced concrete is a vulnerable material requiring constant care and maintenance. Moreover, the brutalist heritage that has come down to us is not yet universally recognized, making the idea of recovering, healing, and preserving structures from the second half of the 20th century less commonly conceived. These conditions have often led to the degradation of buildings long abandoned and disused, now in seriously deteriorated condition due to inactivity. Understanding the abandoned reinforced concrete heritage and rethinking its design, structural, and technological aspects means addressing an increasingly relevant issue. Rethinking reinforced concrete construction and rejecting demolition, allows for a complex and challenging path: "it is an opportunity to design a second chance of redemption for "fragile" modern buildings after the end of the Modern Movement"[2]. Aware of the 'vulnerability' of modern buildings in relation to their longevity, this essay aims to contribute to a growing body of literature focusing on the delicate issue of diagnosing and caring for post-World War II buildings. It seeks to establish models of intervention and good practices for the recovery of built heritage. The 2021 Pritzker Prize[3], awarded to architects Lacaton and Vassal, confirms the growing attention to this issue, which has become increasingly central in recent years. Currently, most interventions focus on structural consolidation and retrofit actions of building envelopes, as they represent the building's face and regulate its relationship with the city. The objective of this essay is to identify practices of space reuse capable of spontaneously reactivating an initial phase of building regeneration. To this end, two disused buildings are analyzed, considered useful for establishing general criteria and good practices for interventions that see the idea of re-inhabiting the existing structure as a possible recovery strategy. Vittoriano Viganò's Marchiondi Spagliardi Institute in Baggio (Milan) and Alberto Galardi's former Marxer Pharmaceutical Industry in Loranzè (Turin) are two emblematic buildings of this type (**Fig 1**). Both are located in peripheral areas, away from built-up contexts , and were constructed for functions that no longer meet current demands. These factors contributed to their abandonment and degradation. It is believed that reactivating these buildings could revitalize entire areas because "it is precisely the suburbs that are the city of the future, where human energy is concentrated and which we will bequeath to our children"[4]. Galardi and Viganò were awarded the 1962 AITEC National Prize for their architecture together with illustrious figures such as Nervi, with the following motivations: "The architect Alberto Galardi of Milan for the importance and idealism of the work presented. [...] Architect Vittoriano Viganò of Milan,

for the conspicuous value of architectural unity expressed in the Marchiondi Institute in Milan, in which cement is the protagonist"[5]. The prize, announced by the Associazione Italiana Tecnico Economica del Cemento (AITEC) in collaboration with the magazines Domus, Casabella, Stile Industria, and Industria Italiana del Cemento, has the aim "to make known the highest Italian developments and the applicative characteristics of concrete in the most important architectural and technical works, which means to make them recognized also on a cultural [...] and social level"[6].

1. THE MARXER INSTITUTE AS AN EXAMPLE OF THE REDEVELOPMENT OF OUTDOOR SPACE

The Marchiondi Spagliardi Institute designed by Vittoriano Viganò arose from the need to relocate, following World War II bombings, an educational facility for difficult children previously located on Via Quadronno in Milan. The choice of materials and colors used, as well as the arrangement of the buildings in a comb-like layout relative to the main body, reflect an architectural vision integrating functionality and aesthetic value. Recent decades have seen renewed interest in this building and efforts to protect it, thanks to administrative actions that have revalued it "as an eminent work of 20th-century architecture, up to the recent monumental constraint placed by the Lombardy Superintendency of Architectural Heritage"[7] . The building was constructed on the western outskirts of Milan, in Baggio, due to the need for an isolated environment to protect the children from negative city influences. However, the decentralization contributed to social isolation from the surrounding community, which never really engaged with the building. The complex, with its relatively tall and compact building blocks, appears as an alien object in the sparse built fabric of the Milanese suburbs. The arrangement of buildings along an east-west axis and the presence of a concrete perimeter wall, necessary to comply with regulations, further accentuated this sense of separation, also due to the absence of a street onto which the dormitory structure would face. Thus, the complex became completely isolated from the urban context. The only potential link to the outside space was the surrounding green area, but this was never integrated into the project. Since abandonment, nature has been re-appropriating the concrete, almost marking the desire for this missing link. The former Marxer pharmaceutical factory designed by Alberto Galardi on a commission from Adriano Olivetti is located in a more rural area, surrounded by greenery near Loranzè, a small municipality in the province of Turin about 6 kilometers from Ivrea, an important industrial city known for being the hub of Olivetti's activities[8]. This proximity provides easy access to main urban infrastructures while maintaining a certain distance to preserve the natural integrity of the site. Unlike the Marchiondi Spagliardi Institute, the former Marxer factory seeks to establish a harmonious dialogue with its surroundings: a green buffer zone, originally intended as a park, frames the building and isolates it from the external system. The decision to place the building in a green area reflected the desire to create a healthy and stimulating working environment where

workers could benefit from being close to nature, purposely chosen away from the chaotic urban center. (**Fig.2**) Olivetti's influence on Viganò and Galardi's designs can also be perceived in the design of outdoor spaces and the relationship with the natural and urban context. In the case of the Marchiondi Spagliardi, the relationship with the surrounding context is perhaps less pronounced due to the type of function it houses, closed in on itself; the Marxer, on the other hand, follows an approach that fully reflects Olivetti's ideas. However, neglect and lack of maintenance have led to the progressive degradation of both the building and its surroundings, compromising the initial link between architecture and landscape. A proper good practice for intervening on the Marxer—being immersed in a green area and built to create a dialogue with neighboring areas—could involve using green spaces as a connecting element between the two neighboring municipalities, creating a green lung and large urban park that serves as a hinge for the small surrounding towns. Regarding the relationship between the building and the context, the Marchiondi Spagliardi can learn from the Marxer to establish new forms of dialogue with external spaces, reconstructing the failed relationship with the adjacent green space to interact with the inhabitants.

2. THE MARCHIONDI INSTITUTE AS AN EXEMPLARY CASE FOR FUNCTIONAL REUSE

The architectural structures of the Marchiondi Spagliardi Institute and the former Marxer industry exhibit innovative characteristics for their era. The comparison shows how the use of reinforced concrete was interpreted differently to meet specific functional requirements. In both projects, the use of exposed concrete, which is constantly subjected to atmospheric agents and has lacked proper maintenance, has led to degradation requiring urgent restoration work and the implementation of good practices for functional reuse. In the case of the Marchiondi Spagliardi Institute, Viganò's (**Fig. 3**) decision to use metal formwork for the concrete casting instead of wood has led to cambering of the walls. In the former Marxer industry, the degradation of reinforced concrete is evident in the exposed surfaces and construction details. The Marchiondi Spagliardi Institute uses a trilithon structural system, with a double internal and external structure providing stability and three-dimensionality to the elevation. This system allows a clear distinction between load-bearing and non-load-bearing elements, creating a dynamic effect between the static masses of the service blocks and the beam-and-pillar structure. The clarity of the structure ensures it can never be confused with non-load-bearing elements, usually transparent or finished in primary colors. Similarly, in the former Marxer industry, the use of reinforced concrete is innovative: a porous and open filter-façade consisting of concrete elements serves as both a load-bearing structure and a system of skylights, giving the building a balance between functionality and aesthetics. The structure expresses the plasticity and versatility of reinforced concrete, used in various forms to meet the project's functional requirements. A remarkable play of light and shadow, achieved through natural lighting solutions using polycarbonate skylights and

facades shielded by concrete elements, is a distinctive feature of Galardi's design. The interior of the Viganò building is specifically structured for its intended function: an elegant spiral staircase provides access to the structure's four floors, with rooms connected by a long, bright corridor characterized by extensive glazing. A series of further spiral staircases in the hallway at the entrance to the various floors adds an element of abstract lyricism to the complex, together with the pastel colors of the interiors, which are still partly visible although much deteriorated. The bond that was established between the building and its users, the 'difficult boys' of the reformatory, is confirmed by Viganò's words: "Those who really understood the Marchiondi were not the organizers, the school and pedagogical authorities, the colleagues, the architecture critics, who also paid me many compliments: it was the boys. I will not, I think, be able to forget the shout of joy with which they swarmed inside, the enthusiasm with which they took immediate possession of the equipment, the lockers, the clothes racks"[9]. The former Marxer factory, on the other hand, presents a different approach in the configuration of the interior spaces[10]. The four reinforced concrete volumes are designed to house laboratories and workspaces requiring good natural lighting and a healthy environment. The interior spaces are characterized by amplitude, by spaces that can be crossed from side to side, without the use of the partition found in the Marchiondi. Polycarbonate skylights, distributed on the roof, allow light to filter evenly into the interior spaces, creating a bright and pleasant environment for workers. Facades shielded by concrete elements act as solar barriers, protecting the interior from overheating and ensuring optimal thermal comfort. Viganò's design has been thought out by the architect down to the smallest detail, each room reflecting the function it is to house. Viganò leaves no room for flexibility in the spaces[11], but gives the children who are to use the facility the places they need. While this compliance of the building with the required use gives credit to the architect for having designed a building consistent with its purpose, it now makes it difficult to rethink future uses. Several solutions have been proposed in recent years, but the deteriorated condition in which the Marchiondi currently stands imposes good restoration practices on the existing building to prevent the problem from occurring again. Most of the projects that have been proposed for the restoration of the Marchiondi have imagined functions such as student halls or dormitories. Even the latest project approved by the PNRR (National Plan for Recovery and Resilience) envisages a university residence for students. However, to avoid abandonment again, it is important to envisage some functions of a public nature, capable of bringing the community closer to the building—neighborhood functions, suitable for the daily use of the space, re-establishing a relationship between the internal and external realities, directly with the neighborhood. Architecture for university housing can certainly become a driver of urban regeneration by attracting external students, but this type of use must be flanked by others that encourage citizens to use the Marchiondi's spaces to ensure reliable and lasting use. Through these actions, university housing can be transformed into a catalyst for processes of social and cultural

change, capable of acting at multiple levels and scales, supporting actions to include rather than exclude, becoming 'an architecture free from that monogamous conception that wants it to be the bride of a single interest or a single idea. A pragmatic-utopian architecture that aims to create socially, economically and environmentally perfect places[12].

Due to the current focus on the Marchiondi, the various possible actions proposed, and the intention to return it to the neighborhood by introducing public functions that reactivate the building, the Marchiondi may be a case of good practice to be analyzed for the reuse of the Marxer. The two projects reflect Adriano Olivetti's ideas of integrating aesthetic and social functionality into the project. Indeed, the Istituto Marchiondi Spagliardi, with its focus on pedagogical principles and the creation of spaces that foster socialization and personal development, reflects Olivetti's approach to education and social welfare. The layout of the buildings and the choice of materials create a stimulating and comfortable environment for the children housed. The use of exposed reinforced concrete and attention to construction details are the

12. Bjarke Ingels, *BIG. "Yes is More. An Archicomic on Architectural Evolution"* (Cologne: Taschen, 2009)

distinctive elements of Viganò's design. Similarly, in the Marxer, Galardi designed the building with natural lighting, ventilation, and comfort in mind, creating a healthy working environment. The innovative architectural solutions he used are examples of how design can improve the quality of life for workers, in line with Olivetti's ideas. Olivetti's vision of architecture that focuses on human well-being and the quality of space is a crucial element in the future of projects to restore Brutalist buildings such as the Istituto Marchiondi Spagliardi and the former Marxer factory. Olivetti's influence extends to a holistic approach that considers the social and environmental impact of architecture[13]. This contemporary vision can serve as a guide for renovations that not only preserve the historical and structural integrity of the buildings but also make them relevant and functional for contemporary communities. The two buildings can thus mutually exemplify, on different themes, a regeneration process that puts the design of the existing at the center. In short, post-war Brutalist architecture, representing a heritage of architectural innovation, structural attention, and social vision, offers an important opportunity. The challenge of contemporary architecture is, therefore, to pose the problem of the restoration of the modern, of the adaptive and functional reuse of abandoned places, proposing a project tailored to the existing, capable of adapting to what precedes it as much as stimulating collective interest in a building to reactivate a regeneration that is not just punctual but widespread on an urban scale, while respecting the principles of quality, functionality, and well-being of the original projects. "Transforming these points of rupture of the urban fabric, these points of laceration of the harmonic expansion of the city's structures into points of suture—in which to undertake growth once again according to large parameters, appropriate to the life and function of the contemporary city—is a task of the utmost importance; in that it is not only worth recovering the very areas in which one intervenes, but also influencing the city's more external development'[14]. ■

BIOGRAPHY

Bianca Maria Rodriguez, architect, born in Naples in 1992, graduated in Architecture in Naples from the University of Naples Federico II in 2018 with a thesis in architectural design titled "Baghdad Design Center: a new building on the remains of the Old Governorate Building" on the topics of infill intervention in a twentieth-century building in Baghdad. During his university years she participated in several competitions, winning some of them such as the competition entitled "Neapolis. Living as a student" awarding herself an internship at Atelier Alfonso Femia studio. She has collaborated in university courses on the topics of restoration of the modern and the existing as project material. Her interest in research and academy led to a PhD from the University of Naples Federico II that was completed in 2023 with a thesis entitled "Gio Ponti. The urban fifth in the dialogue between the places of living" and was a speaker in a lot of conferences such as the 14th fib Symposium on reinforced concrete issues with a contribution entitled "The role of structure in the dialogue between The places of living in Gio Ponti's projects." She currently continues to collaborate with the university.

Chiara Assante, architect, born in Benevento in 1999, graduated in Architecture in Naples from the University of Naples "Federico II" with highest honors. Her thesis, titled "Living with risk: the case of Castel Volturno," addresses hydrogeological risks in the Lower Volturno Valley, proposing strategies for coexistence and mitigation. Currently holds an ICAR12 research grant, contributing to the HORIZON EUROPE Knowing project on climate change. She has collaborated with architectural firms, participating in the design of public works and renovations. She took part in international conferences such as "Climate Change and Cultural Heritage IFAU23" at the Vanvitelli University in Caserta and the "Seminar on Architecture and Urban Culture" in Camerino, where his thesis work was awarded. She has attended advanced courses such as Villard23 where she received an honorable mention, showing a strong commitment to sustainable architecture and urban regeneration.

TOWARDS A HISTORY OF INTERNATIONAL TRANSFERS IN LARGE-CONCRETE PANEL SYSTEMS

PEDRO IGNACIO ALONSO
PONTIFICIA UNIVERSIDAD CATÓLICA DE CHILE

#09

ABSTRACT

This paper explores how, during the twentieth-century, novel technologies for the prefabrication of modernist housing became powerful tools for the construction of a new society. After the Second World War, in particular, the development of prefabricated concrete panels drastically transformed the techniques used to build the modern world. Manual labour was replaced by automated mass production, and new concrete elements were used in billions of square metres of housing around the planet. Before turning into what many consider a dull face of our cities today, the stunning image of a concrete panel soaring through the sky appeared in all forms of popular culture, reshaping our cities. One of the most relevant features of these systems relates to the manner in which they were created in countries such as France, Denmark, Sweden, the Soviet Union et al., to be then transferred to many different contexts in the Americas, Africa, Asia, and Oceania, contesting the highly rational and standardised nature of the systems with their reception in the various local political, technological and climatic conditions where they were received and readapted. The paper discusses the way in which concrete panel systems spread across the world, reflecting on their influence from the second half of the twentieth century to the present.

Almost a Piranesian scene, wild grass is growing around a 2.6-ton large-concrete panel we found in 2009. Ruined and abandoned, it had fallen to the ground at a former industrial site in Quilpué, Chile. Upon close examination, this was a facade panel, with joining features that could be identified as belonging to the French Camus panel system for the prefabrication of housing, patented by Raymond Camus in 1948 and thereafter exported to many countries **(Figure 1)**.

But in this Chilean case, the jointing rim was also heavily indented, a telling mark of an adaptation made in the Soviet Union to reinforce the buildings' structure against earthquakes, like the one that hit Tashkent in 1966, providing the USSR with the opportunity to test the adaptation of Camus into the I-464 series. But the panel in Quilpué had another particular feature rather unknown to both French and Soviet systems: it was carved on one side, in order to save concrete while adjusting the wall's thickness to the economic and climatic conditions of Cuba, the country that received the system as a donation from Nikita Khrushchev to Fidel Castro's early revolutionary years[1]. This ruined panel, however, was not found in Cuba, Russia, or France. It rather belongs to the long-dismantled KPD plant, a factory provided by the USSR in support of Salvador Allende's *Unidad Popular* government (1971-1973). Once discarded as rubble of socialist modernism, and half-consumed by vegetation, this piece of concrete became a kind of archaeological find and almost a fossil, holding material evidence of a global history that well summarises a geopolitical line of gradual transformation that, in the span of nearly 30 years, drew political, economic and social threads connecting architecture and building technology in France, the Soviet Union, Cuba, and Chile.

This was neither an isolated case, nor it was exclusive of the Soviet Bloc. Dating from the 1950's, the Danish Jesperson & Søn system was extensively used in Denmark (Høje Gladsaxe, Rødrove, Vildtbanegaard, etc.), before being exported to the United Kingdom, Canada and the United States. In 1964, it was brought to Sweden by the A-Betong company, transforming it into the A-system Byggelement *AB*, which was used to produce projects such as the Helsinborg compound (1965). Through A-Betong, the A-system's adaptations resurfaced in Shoaiba (Abu Dhabi) and in Saudi Arabia through the Alrashid A-Betong Company (1976). Also in Sweden, the Ohlsson & Skarne's S66 system (1960's), was reportedly transferred to West Germany, Canary Island, Kuwait, and Venezuela; as well as the British BRECAST system, which was developed during the 1970's and was seen in Indonesia and extensively applied in the Middle East until the mid-1980's, albeit transformed into BREKIT, with a lower cost and greater adaptability, reportedly implemented in Southeast Asia and former British colonies in Africa.

Another case is P2, a system from the GDR that, having absorbed elements from the Soviet II-35 system, became the East German WBS-70. Later transformed into the W-70 series, it was sent to Poland, where it arrived as the WK-70 system. And while it was not further exported

1. Pedro Ignacio Alonso and Hugo Palmarola, "Tropical Assemblage: The Soviet Large Panel in Cuba." In *STS in Latin America: Beyond Imported Magic*, ed. Eden Medina, Ivan da Costa Marques, and Christina Holmes. (Cambridge, Massachusetts: MIT Press, 2014), 157-177

to other countries, it eventually evolved within Poland into the SBO and SBM series. And Tracoba, a system patented in 1961 by British engineers Jack Rodin and James Lowe for the French company Omnium Technique (OTH), that was active in Europe, Africa and North America. Several projects were built in France, such as the Cité Massy-Opera (Massy-Antony, 1963); La Castellane (Marseilles, 1966); and the Cité Croix Blanche (Vigneux sur Seine, 1967). It also arrived in Italy to produce the Mirafiori Sud compound (Turin, 1966); in Scotland, the Hutchesontown project (Glasgow, 1968); in Spain, projects in Alcalá de Henares (1969); and Ciudad Badía (Barcelona, 1969); and in the United States -turned into Tracoba V- with the Yorkers project (New York, c1970). During the 1970's, the Danish Højgaard & Schultz company, in collaboration with the Italian Recchi Ingegneria, transformed Tracoba to build a large housing compound in Tripoli (Libya) (Amtered El-Abidi, Ghazali and Nor Azhari Azman 2014), incorporating perforated panels, balconies, arches and motifs in an attempt to engage with the local cultures **(Figure 2)**.

As with the fallen panel in Chile, the arabesque motifs added to Tripoli's facade components are physical traces of international processes of typological resignification that could only be fully grasped when looking at the way British engineers (Rodin and Lowe), and a French company (OTH), would be taken by a Danish and Italian consortium (Højgaard & Schultz and Recchi Ingegneria) to make a new urban development in Libya. During the post-war period, similar practices could be observed in many different contexts, including manifold journeys of concrete panel systems from Eastern and Western countries to Asia (Mongolia, Vietnam, Nepal, China, Japan, Taiwan and North Korea); to Africa (Morocco, Egypt, Zaire, Gabon and Zanzibar); to the Middle East (Iraq, Kuwait, Syria, and Bahrain), and to America (the U.S., Canada, Cuba, Colombia, Venezuela and Chile), to name just a few. The study of these buildings must be accounted from within the genealogy of systems they belong to. This is a history of movement and exchange in the formation of a global network, where not even the smallest possible panel should be studied in isolation.

Stretching the world in all directions, we thus observe how panel systems have moved along routes trespassing national boundaries and connecting continents. Sometimes, these operations consisted in selling out a system's patent (i.e., Camus to the Soviet Union). Other times, an entire factory was either sold or donated to another nation (i.e., I-464 sent to Cuba or Chile), or they were the result of technical missions sent to leading countries to learn from their experiences (i.e., the Swedish D4 group touring Denmark and France in the 1950's, or the U.S. Delegation to the USSR in 1970)[2], or belonged to technical expertise shared by travelling experts to developing countries (i.e., GDR architects and engineers in North Korea or Zanzibar). At the same time, these journeys were often the outcome of purely economic ventures (i.e., Tracoba expanding its market to the US), or a mixture of economic policies with political influence (the USSR in Eastern Europe and Asia), post-colonial impulses

2. James Wright, "Industrialized Buildings in the Soviet Union: A Report of the U.S. Delegation to the U.S.S.R. National Bureau of Standards Special Publication 334." In *U.S. Department of Commerce*. (Washington D.C.: U.S. Government Printing Office, 1971)

(i.e., the Italian Recchi taking Tracoba to Libya), or the wishful attempt at solving the problem of social housing in the Third-World under the banner of technical assistance (i.e., the Ford Foundation sponsoring Canadian based research to implement the UCOPAN system in Egypt, India, Nepal and Bangladesh)[3]. We could follow these routes, accounting for the connecting points that, having some similar economic or political conditions, would set the ground for the transnational movement and the transformation of manifold architectural species, within the making of a range of mechanisms that allowed systems to trespass national borders and customs areas in commercial or diplomatic missions, often under the banner of cooperation, or to assist for recovery after natural disasters.

Thinking about a truly international architecture, and about regionalisms, what matters is to see how specific cultural, political and technological contexts challenged, distorted or even contaminated the often-considered stiff typologies of closed systems of prefabrication, allowing us to observe the various processes of hybridisation as they actually happened. Only by following this path we could truly see the regional and the idiosyncratic becoming acting forces in shaping supposedly generic systems. Not an easy task, as it means to look for literature that would give traces on the system's various paths or, in absence of such literature, to survey the actual buildings, learning to recognise, for example, Camus in KPD or Jesperson in Alrashid A-Betong. For instance, created in 1958, the Chinese 9014 system seems to be a rare combination of the Soviet K-7, I-335, I-464 and I-464A series (an unthinkable mix only possible given their similar joining systems). By 1963, the system started to be used in Beijing's Tuanjiehu district, developing a rather unique panel type consisting of a rigid outer frame that, should there not be enough concrete to complete the building, would enable manual labour to fill the panels with alternative materials. In another case, the Hungarian reception of I-464 in the Tulipános system (1963) was developed as a way to fight the rigidity of the housing block typology by adding a floral motif in special panels. Described by Virág Molnár as the *Tulip Debate*, such new features are telling on the quest for combining the highly industrial with the local labour, by means of organic imageries. The Romanian 770 system of 1975 (yet another version to the soviet I-464 system), also sought to absorb the foreign technology, transforming the isolated building into one that could turn around the octagonal corner of the city block, forming a continuous facade within the traditional city. This rotation is allowed by a number of special panels and floor slabs, enabling the system to incorporate a rather unique urban concern for these kinds of technologies. Likewise, in 1958, the Swiss IGÉCO system had explored the possibility of having special panels to allow building blocks to slightly bend, as in La Gradelle complex in Genève. Initially an adaptation of Danish Larsen & Nielsen system (1950s), IGÉCO evolved into a technical and typological refinement that is not usually associated to the architecture of prefabricated concrete panels, to the extent that Franz

Figure 3. Staggered axonometric models of 30 large-concrete panel systems. Credits: José Hernández and Pedro Ignacio Alonso.

Graf has compared it with *haute couture*. This is telling of the capacity of systems to introduce variation, for Larsen & Nielsen is the same system that in the United Kingdom produced the Morris Walk Estate in South-East London, and the infamously collapsed Canning Town in Newham, East London (1968), and that by 1975 had expanded to 15 countries, including the Netherlands, Norway, Hungary, Sweden, and Turkey

The success of large-concrete panel systems, at least in terms of both adaptability and the number of square meters built (with some estimations considering no less than 5 billion m^2 worldwide)[4], would lead us to believe that such achievements are not despite of the systems' elementary closed kit of standardised panels, but rather because of it. Freed from having to comply with the multiple externalities of the long-standing search for open systems of prefabrication (with their whimsical look for a universal modular coordination), they could change and adapt by gradually adjusting their inner component arrangements. **(Figure 3).**

During the twentieth century, in fact, hundreds of systems were conceived, patented and set in operation, creating virtually infinite numbers of variations, series and transformations. This session aims at portraying this history, and the logics underpinning the production and the differentiated global provision of panel systems within architectural geopolitics. Beyond the systems, the work would reveal the interacting elements at play in the manifold global journeys (and political and commercial controversies) undertaken by concrete panels. ■

THE BIRTH OF STAVOPROJEKT, A SOCIALIST ATTEMPT TO COLLECTIVISE DESIGN PRACTICE AND STANDARDISE BUILDINGS AND TECHNOLOGY

PETR VORLÍK
FA CTU PRAGUE

#09

ABSTRACT

After the Second World War, Czechoslovakia became part of the Eastern Bloc of Europe and subject to the political influence of the Soviet Union. This change accelerated and was confirmed when the Communist Party seized power in 1948. Left-leaning architects were prepared for the situation and started to collectivise the work of design. In 1948, Stavoprojekt was founded as the state design organisation, which brought together architects, engineers, and other related professions. Its activities were mainly focused on the post-war economic revival, traffic and industrial infrastructure, centralised spatial planning, and solving the housing shortage. Typification (of buildings and elements) and later also prefabrication were significant tools widely applied in the field of housing. In order to efficiently achieve its goals, Stavoprojekt was affiliated to Czechoslovak Construction Works, which collectivised the production of building components. At the same time, the Research and Typification Institute was established, and its task was to prepare the basic manuals for typification. In the circumstances of postwar scarcity, however, reality lagged far behind the plans, and prefabrication in the late 1940s and early 1950s focused mainly on subcomponents of a building's structure that did not require demanding technological solutions or the use of large amounts of scarce steel. The typification of whole buildings (especially buildings used to house smaller amenities) also developed slowly and was only promoted in a few cases. It was not until the 1960s and 1970s that prefabrication and typification were fully implemented. Nevertheless, the early search for universal concepts in the conditions of the collectivised economy of 1948–1953 is a remarkable example of the possibilities and limits of this modernist idea. The impact of the attempts to centralise design practice and attach it to construction production was far-reaching and continued to be felt in the ensuing decades.

1. COLLECTIVISATION

In February 1948, the Communist Party in Czechoslovakia took advantage of the government crisis and seized power. A new socialist society was to be built through nationalisation and collectivisation, the first wave of which impacted mainly agriculture and industry. The straightforwardly totalitarian process also affected the construction industry. Nationalised construction companies became concentrated within one centrally controlled company – Czechoslovak Construction Works. The arguments used for these imposed decisions and processes were the needs of postwar economic recovery, the idea of increasing the efficiency of central planning and direct rule by politically motivated workers' professions in the place of a profit-oriented market economy, and, last but not least, the move towards an egalitarian socialist society and general prosperity.

The design organisation Stavoprojekt was established as a part of Czechoslovak Construction Works in 1948 in order to ensure that there was a fully integrated process in place between investment planning, the design process, the production of building materials and components, and project implementation. Not surprisingly, a similar idea for a central design institution, collectivisation, and the rationalised organisation of the construction industry was being considered by domestic radical left-wing architects with links to CIAM and the Soviet Union – in particular the Block of Architectural Progressive Societies (BAPS) and the Working Architectural Group (PAS). Alongside them, however, other (not just left-wing) architects found a place for themselves in Stavoprojekt's structures, which enabled them to have access to large-scale state projects.

2. THE STRUCTURE OF STAVOPROJEKT

Stavoprojekt was structured along the lines of a meticulously thought-out and strict hierarchy that was formulated in the initial directives. This hierarchical arrangement, supposedly inspired by the Soviet Gosplane, was intended to support the rational planning, allocation, and management of work. The highest authority was the directorate. The first director of Stavoprojekt was Jiří Voženílek, a renowned architect from the Bat'a construction office in Zlín and, therefore, someone who had extensive experience with 'American' Taylorist methods of design work and construction. Jiří Voženílek was also a member of the above-mentioned PAS group, which based its socially oriented visions on a rational scientific approach – graphs, tables, organograms – inspired by Neue Sachlichkeit and Soviet constructivism (e.g. in urbanism especially by Miljutin). His group colleague Karel Janů became director of the Czechoslovak Construction Works and directed his efforts to put mass prefabrication into practice.

The 'research centre', based in Prague, became a key part of the institution and it was soon given the name the Research and Typification Institute (STÚ). Its remit was to collate and analyse information from Stavoprojekt's regional departments and specialised ministerial departments and to work on the rapid preparation of national typification documents.

Another central creative department of importance was the Institute for Urban Planning based in Brno, the existence of which is an illustration of how important large-scale regional planning and zoning was for the postwar recovery and for the socialist reform of the economy.

The preparatory, conceptual phases of (mainly investment and urban) projects were to take place in the directorate, while the subsequent elaboration and implementation of the projects would be transferred into the hands of regional design departments. In the regions, projects were developed in the Regional Architectural Studios, and in the Regional Engineering Offices. The Regional Architectural Studios (the word 'studios' eloquently illustrates how, despite the prevailing technocratic rhetoric, artistic ambitions that were unwilling to give up their interest in form survived) focused on addressing the housing shortage and increasing production. The Regional Engineering Offices were mainly devoted to the reconstruction of transport infrastructure and large-scale interventions in the landscape, especially rail and road networks, water management works, and operations connected to the collectivisation of agriculture.

The predictability of processes and planning was to be achieved through the standardisation of the work and roles. The aim then was to establish a standard of performance for each type of work or employee, and how a design office should be staffed, and on that basis to create an effectively functioning and collaborative workplace that could fulfil the role required of it within the larger frame of socialist planning.

The coordination of work at Stavoprojekt proceeded through mass communication – directives, instructions, bulletins, and correspondence (in 1951, among other things, a directive on issuing directives was issued). A substantial role was to be played by meetings between managers and specialists across Stavoprojekt's units, by meetings with representatives of building materials and components production, and, last but not least, by committees that in the beginning were euphemistically called production boards.

3. TYPIFICATION

Stavoprojekt's introductory documents had already indicated that all departments were required to use the standardised designs and construction technologies prescribed by the directorate. Therefore, typification specialists played a key role as members of the work teams at the regional design institutes. Their role involved collecting data from ongoing projects and sending them to the directorate and the STÚ, where the results were evaluated, and the most successful (i.e. usually the most cost-effective) designs and implementations were declared to be models or 'types'. And the regional centres also assisted with testing trial projects and prefabricated modules created at the STÚ.

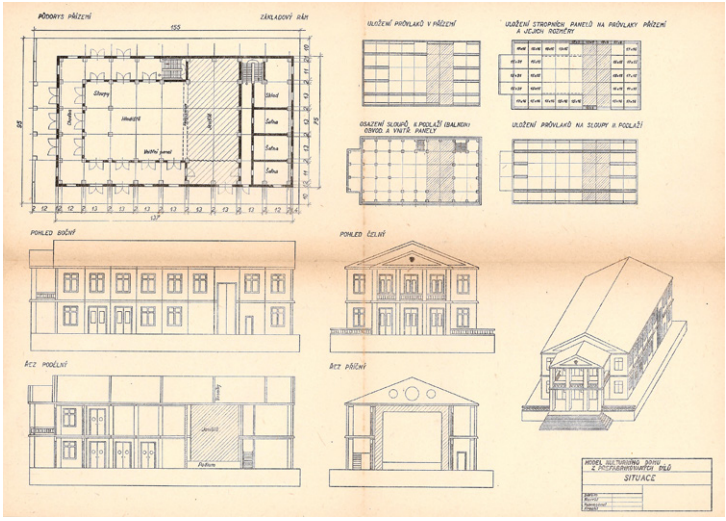
Regular meetings were also held among the central and regional typification specialists to discuss the limits and potential of existing and emerging typified projects. Broad discussions took place not just on efficiency and technical difficulties but on issues relating to the application

of the socialist-realist style, which, according to the participants in these discussions, was in no way at odds with the unification of projects and building components. On the contrary, it was believed that to flesh out this style with atypical parts and details would give rise to distinctive, original, and, at the same time, local variations with Slavic undertones. The first comprehensive prefabricated products for residential construction were, unsurprisingly, thus elements of decoration – cornices, ornamental mouldings, insignia plates (similar to elements for 19th century tenement houses, but different in material and symbolism).

The Research and Typification Institute published a number of manuals and instructional materials that were to varying degrees binding. Their value as a resource lay mainly in the summary and analysis of successful projects (including foreign ones) and linking them to real products in the construction industry. As early as 1949, the STÚ produced a Survey of Works, which focused mainly on the issue of modules and building sections with predefined dimensions and thereby set the stage for the planned massive unification.

An important step in the direction of the successful planning and implementation of buildings, as of 1 January 1951, was the use of 'standard costing', i.e. detailed tables of standard products in use and the associated costs as well as instructions for production. For these purposes, at the end of each year the individual branches of Czechoslovak Construction Works issued catalogues for the following year, and the prices throughout that year had to remain fixed. The aim was not only to plan the production of building components in a coordinated way and in relation to planned investments, but also to provide an overview of the costs of construction and to be able to apply a rationalised approach to managing cooperation between production and design.

In 1951, the STÚ published the first Typification Handbook; 16 more volumes followed in 1952. The Typification Handbook offered tested, standardised solutions – a) the selection of whole standardised building types, b) the standardisation of functionally complementary and interchangeable parts of buildings, and c) the standardisation of building components. Soviet examples and standards were expected to become the official source for these compendia and projects. However, the real content was more likely to be local tried and tested models and, for the less tested, at least basic description of examples from Western Europe (e.g. garages). Every standardised building was presented using reference examples and in the form of a recommended standardised design. This included basic plan documentation, details, and the geometry of the more complicated elements, drawings on technical infrastructure, statics calculations, budgets, and additional tables or descriptions.



From 1953, the STÚ also published catalogues of family houses for self-build construction, the aim of which was to remedy the insufficient amount of central state construction of apartment buildings. In later years, a number of detailed manuals and even the production drawings for entire systems were published.

In 1951, Stavoprojekt set up a Special Department for Heavy Assembly, i.e. for the extensive use of large prefabricated reinforced-concrete components, and from 1952 there was a research group at STÚ as well that focused on flow construction and creating network diagrams of the construction process. To accelerate and increase the volume of construction there was also an idea to eliminate the seasonality of production by extending construction activities into the winter season. This had little effect, however, on the housing stock in the 1950s. In the early postwar years typification was premised mainly on searching for spatial and operational designs that could be universally and recurringly applied, and less on the actual composability of buildings made of prefabricated components (except in the case of industrial buildings and engineering structures). Prefabrication was concentrated more on the reduction of costs, on sophistication, and on the production of only the most efficient building components. As a result of the postwar shortages and the earmarking of strategic materials (especially steel) for selected buildings and products, designers, despite their past interwar avant-garde experience and declarations of progressiveness, were left with the only technologies available to them, which were the traditional technologies (bricks and blocks, plaster, wood). In 1958, moreover, the costs of constructing typified buildings that made more use of prefabricated materials was 18 % higher than the costs of constructing buildings using traditional technologies.

4. INDUSTRIALISATION

During the first postwar years as part of what was called the two-year plan there was surprisingly little use of prefabricated materials. Instead, there was a continuation of the interwar model of the construction industry, and central planning was unable to offer any more comprehensive alternative in the given conditions of material scarcity. The most extensive use of prefabricated components was seen in the construction of the Solidarita cooperative housing estate in Prague (1946–1961), designed by František Jech and Karel Storch (both of whom had worked in the residential department at BAPS) and Hanuš Majer, where a separate company called Montstav was even established to produce prefabricated components on site; and in housing construction in Zlín, which continued the work of the Baťa company's interwar construction office. Other, alternative inspirations were sought in Scandinavia and, unsurprisingly, this involved building wooden family houses, generically called Finnish houses, modified in Czech conditions for prefabrication. Journals also frequently quoted examples from Germany and the Netherlands in connection with prefabrication.

Nevertheless, the 'block' system was the most common form of prefabrication in the housing estates of the 1950s. This involved laying out bricks or blocks of masonry in factory and then transporting them to be fitted on site. The ceilings on the block walling were formed from reinforced-concrete panels or monolithic reinforced concrete with lost formwork made of ceramic blocks. The surfaces of the walls were coated with plaster, while the windows, doors, and roof trusses of the pitched roofs were made of

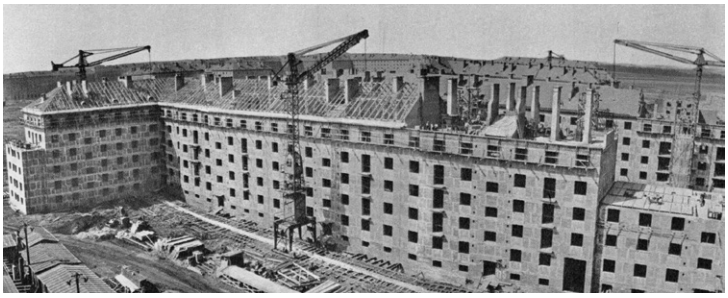


Figure 1. Plan for a child's model of a prefabricated house of culture (Source: Čestmír Bárta – Ladislav Zástěra, *Modely panelových staveb*, Praha 1957).

Figure 2. Residential building in Ostrava, constructed using 'block' system technology (Source: Karel Storch (ed.), *Nová technika a architektura v Československu*, Praha 1961).

Figure 3. Residential building within G55 system (Source: Karel Storch (ed.), *Nová technika a architektura v Československu*, Praha 1961).

wood. The rationality and the large modules used in the block system were naturally reflected also in the simple, robust, and rhythmic composition of the façade. This system was applied on an enormous scale in the construction of housing estates located in the country's new hubs of heavy industry – in Ostrava, Havířov, Příbram, Ostrov, and Plzeň.

At the same time, however, experimentation began in 1953 with the 'Type G' (after the city of Gottwaldov, renamed for the first socialist president of Czechoslovakia, which is now again called Zlín), which involved the complete deployment of prefabricated reinforced-concrete components. Its basic structure consisted of the flat panels of the load-bearing façade, transverse walls, and ceilings with modular spans of 3.6 metres. Initially, sturdy reinforced-concrete panel strips were inserted into the joints of the wall panels, which allowed the gaps to be filled with concrete, thereby effectively strengthening the joints, while at the same time characteristic vertical lines formed along the façade, resembling pilasters, topped with a similar attic or crown cornice design. The structurally less significant joints between panels could be left visually exposed on the façade and in this way the building no longer concealed its compositional form. Flat roofs became standard as well. Over the years, there were experiments with getting rid of the aforementioned panel strips, and features of Socialist Realism as well. Experiments continued with installing steel columns in the place of load-bearing walls in the interior, or with the use of various panel surfaces or varieties of panels. Separate and less numerous variations were also built in Hradec Králové (Type HK) and Bratislava (Type BA). There was always high praise in the contemporary architectural press and in discussions for the logical manner in which the systems' structure and tectonics were reflected on the buildings' façade.

The first attempts at the prefabrication of apartment buildings in housing estates did not last long, but they were a foreshadowing of how things would develop in the ensuing decades. From 1957 they were followed by the development of systems T-01-B, T-02-B, etc., and these gradually evolved into the extremely successful T-06-B and T-08-B, which then sprang up in multitudes across Czechoslovakia in the 1960s and 1970s. They were followed by the more developed VVU-ETA, the Type OP, which offered a variety of façade panels and claddings, and the Type P, which was developed at the end of the normalisation period but was not used very much in practice and which allowed for various ways to work with the plasticity of the façades and corners and create diverse roof landscapes. Similarly, there was no shortage of advances in the development of prefabricated reinforced-concrete frames, which culminated in the MS-71, MS-OB, and Konstruktiva types that in the 1970s and 1980s could be found in almost all the buildings that housed common civic amenities. It should be added that the successes achieved in the mass production of complete reinforced-concrete systems gradually resulted in the triumph of quantity over quality (in an effort to fulfil the socialist five-year plans) and the extensive architectural 'homogenisation' of the environment of Czechoslovak housing estates.

5. APPENDIX

Stavoprojekt grew quickly from a small group of enthusiastic supporters of the idea of collectivism and the technocratic management of a socialist country to become a giant institution. During the very first months of its existence it attracted more than 1,200 employees, and by 1952 it had more

than 11,000. As a result of the restrictions on free enterprise it continued to grow until it was one of the largest architectural design organisations in the world. Stavoprojekt retained its original structure and functions until 1951, when it ceased to be subordinate to Czechoslovak Construction Works, and in 1953 it was established as a separate 'national enterprise'. Numerous changes ensued between then and the change in regime in 1989, the effects of the initial decisions and the huge institution's technocratic management nevertheless continued to be felt. While the rigidity of the central office and subordination to Czechoslovak Construction Works were no longer there, the division of Stavoprojekt into regional branches or specialised branches relating to the work of individual ministries continued, as did the extreme dependency on the rigid socialist construction industry, on the demand to prefabrication, and on political or economic priorities. Architects remained locked in the role of 'mere' employees of a state institution. However, many architects who were witnesses to that time look back today and with hindsight extol the very close collaboration they enjoyed with engineers and various specialists in a focused design organisation. If we look at the architecture that the design institutes created and that managed to break free from the reins of a simple, purely mechanical, quantitative application of prefabrication, we see that even behind the Iron Curtain it very dexterously managed to capture the general transformation that was occurring on the international scene. ■

TRANSPOSING THE DISCOURSE OF INDUSTRIALISED CONSTRUCTION IN HOUSING BETWEEN LISBON AND LUANDA DURING THE 1970S

INÊS LIMA RODRIGUES
DINÂMIA'CET-ISCTE, UNIVERSITY INSTITUTE OF LISBON

#09

ABSTRACT

This paper focuses on the prefabrication process and typification applied in building mass housing neighbourhoods on the outskirts of Lisbon, Portugal, and Luanda, Angola. It explores the transfer of these systems and know-how from Europe to Africa, mapping housing neighbourhoods built at the end of Portuguese colonialism and the transition from dictatorship in Portugal (25 April 1974) to the independence of Angola (1975). The push for widespread housing led to developing large estates on peripheral land, utilising industrialised materials and processes to meet production demands. Large construction firms spearheaded innovation, with prefabrication vital in ensuring economic feasibility and rapid construction times. Portugal initiated its first prefabricated projects during the 1960s. At the same time, the Portuguese state invested in Angola, elevating the importance of housing development in both regions. This article proposes a comparative analysis of housing estates, focusing on the role of large construction companies and the influence of specific prefabricated systems on constructing residential estates in Lisbon and Luanda. It seeks to answer how the introduction of prefabricated design elements led to functional and aesthetic innovations and whether they benefited from foreign expertise. It also investigates the transfer and utilisation of these systems in the Global South, emphasising their profound impact on architectural design and urban planning during the colonial transition. These neighbourhoods drew inspiration from various international models, including Swedish, French, and Soviet systems, and influences from Non-Aligned Movement countries like Yugoslavia and Cuba. Following Angola's independence, additional prefabricated technologies were introduced, facilitating the transition from colonial to postcolonial structures and addressing housing demand while adapting to tropical climates. The comparative analysis underscores how prefabrication influenced architectural design and urban planning during the colonial transition, with construction companies playing a pivotal role in shaping urban landscapes and promoting modern living standards.

1. INTRODUCTION[1]

In recent decades, scholarly focus on the architectural heritage of late colonial and early post-independence periods in sub-Saharan Africa has grown significantly.[2] Within former Portuguese territories, diverse approaches have emerged, investigating the distinctiveness of particular buildings[3], collective housing endeavours[4], or the influence of the Public Works Department's rational design principles.[5] A recent shift in perspective emphasises the global exchange of expertise, materials, and processes, moving away from singular narratives.[6] However, a gap exists in understanding the prevalence and impact of prefabricated techniques in mass housing construction. This paper addresses this gap by examining archival records from specific neighbourhoods and their construction contractors in Portugal and Angola. It aims to elucidate the transnational exchange of expertise and materials, going beyond technical aspects to analyse how prefabricated systems have shaped housing development. Furthermore, it offers critical insights into globalisation's political and economic dimensions.

During the late 1960s and 1970s, Portuguese colonial cities experienced significant transformations in their urban peripheries, primarily driven by housing shortages. To address this, industrialised construction processes were deemed necessary to meet the demand quickly and affordably. The expansion into peripheral areas aimed not only to alleviate housing shortages but also to attract a burgeoning middle class seeking suburban comforts. Adopting prefabrication techniques was instrumental in providing solutions for environmental comfort and sustainability, influenced by geopolitical realities in Portugal and Angola. Through examining housing estates in Lisbon and Luanda, this paper underscores the pivotal role of large construction companies and their adoption of innovative prefabrication methods.

In Portugal, collaborations with foreign companies, such as the manufacture of French "Fiorio" prefabricated panels by the Portuguese factory ICESA and applied by Reaes Pinto or by the Luso-Swedish partnership with MERCATOR-S.A.R.L., led to the introduction of functional and aesthetic innovations in prefabricated developed by Fernando Silva, setting architectural standards for future developments in different locations of Lisbon's outskirts. In Luanda, projects like Prenda and Rangel neighbourhoods, undertaken by Predial Económica SARL (PRECOL) with government backing, exemplified pre-stressed concrete and Le Corbusier's Modulor system, reflecting international design influences. Concrete played a central role in both projects, evident in the beam-pillar system's structural module, the balconies' panels, and the prefabricated elements of the brise-soleils adorning the facades. These architectural choices were both aesthetic and functional, as they facilitated cross-ventilation, optimised form and orientation according to climatic conditions, and minimise exposure to harsh sunlight angles, enhancing interior comfort.[7]

Following Angola's independence in 1975, urban development opened to international collaborations, introducing prefabricated systems from countries like Yugoslavia via NAM countries.[8] The widespread adoption of these systems, known locally as "Blocos dos Cubanos" (Cuban Blocks),

represents a vital housing development for housed foreign helpers and "internationalists" mainly from the COMECON countries, as well as Portugal, Brazil, Sweden, and Italy. It will undoubtedly be interesting to explore the transfer of prefabricated systems developed and popularised in the former Yugoslavia during the 1960s, known as "IMS Žeželj," highlighting the strong influence of tropical architecture launched in the experimental construction site of the "Lixeira-Luanda."[9]

Through archival research, case studies of housing estates, and analysis of urban planning policies, this study offers insights into the complex intersections of architecture, colonialism, and postcolonial urbanism. Contextualising the adoption of prefabrication within broader historical and geopolitical dynamics aims to contribute to a deeper understanding of the legacies of colonial and post-colonial architecture and the ongoing challenges of housing provision in former Portuguese colonial contexts.

2. THE TRANSFER OF THE MODULE, THE PANEL, AND THE PREFABRICATED ELEMENTS IN HOUSING CONSTRUCTION IN PORTUGAL AND THEIR TRANSPOSITION IN ANGOLA

Prefabrication in Portugal started with Ruy José Gomes publishing the first text on the subject in 1952 at the National Civil Engineering Laboratory (LNEC)[10], emphasising design flexibility and efficient construction processes. Despite early experiences in Alvalade, industrial constructions did not initially gain popularity. In 1954, ICESA - *Indústria de Construção e Empreendimentos Turísticos*, partnered with a French company "Société Entreprises de Licence des procédés Fiorio", to establish a factory for prefabricated elements in Póvoa de Santa Iria. This led to rigorous testing and the adoption of prefabrication techniques, as seen in reports from LNEC, including a 1969 report on the ICESA facilities"[11], presenting the various phases of the Fiorio system.

The French Fiorio system was successfully applied by architect Alberto Reaes Pinto in housing developments such as Santo António dos Cavaleiros (1966-1969) and Quinta do Morgado (1969-1970). These developments featured slab blocks and towers constructed using reinforced concrete elements, with Fiorio panels for exterior walls. The integration of prefabricated elements facilitated rapid construction and ensured consistent quality, with tailored finishes in interior spaces.

Architect Fernando Silva played a key role in introducing innovative prefabrication techniques in urban developments such as Alto da Barra urbanisation (1962-1975), collaborating with Luso-Swedish companies to enhance housing projects aesthetically and functionally. Silva, as an architect and founding partner of MERCATOR SARL, maintained high control over the construction process, introducing novel prefabrication systems like the "tunnel-forming" construction system. The establishment of the Portuguese-Swedish construction firm LUSECA facilitated meticulous construction processes, including replacing traditional beam-pillar plate systems with reinforced concrete load-bearing walls, aligning with international construction standards.[12] Despite limitations in internal space flexibility[13], Silva set a

benchmark architectural standard by defining construction elements that provided exceptional comfort in residential complexes. Weekly design meetings from October 1969 enabled knowledge transfer, particularly from Sweden, leading to significant advancements in construction techniques and quality.

The transfer of prefabricated systems and techniques extended beyond Portugal to its African colonies, including Angola. The Portuguese government promoted industrialised construction methods to address housing shortages in colonial cities like Luanda, which were driven by rapid urbanisation and economic growth.

Simões de Carvalho, after his stay in Paris where he specialised in urban planning at the prestigious *Institute of Urban Planning* (University of Paris) and collaborated with André Wogenscky and Le Corbusier (1956-1959), returned to Luanda became head of the Luanda Planning Office.[14] He was crucial in promoting prefabrication in the type-projects for housing, such as the concrete constructions for *rural houses in Quilunda*, encouraged by the *Junta Provisional de Povovamento de Angola* (JPPA), showing architectural elements close to the *Maison du Péon*[15], as the detail of the concrete's gargoyles; also with the *Quinta Palatino neighbourhood*, designed by Weiner, Sert and Schulz in Havana, Cuba.[16]

The Unit Neighbourhood nº1 in *Prenda Musseque*, designed by Simões de Carvalho, Augusto Pereira, and Pinto da Cunha and Rangel neighbourhood, designed by Simões de Carvalho with Lopo Carvalho (1968-1974), were developed with the support of the government and private contractors notably *Predial Económica Ultramarina* (PRECOL), utilised pre-stressed concrete and modular systems to create efficient, aesthetically pleasing housing. Le Corbusier's Modulor system, integrated into these projects, demonstrated the influence of international design principles in shaping the city's modern architecture. Prefabricated elements, such as brise-soleils, balconies, and panels, enhanced the functionality and appearance of the buildings, optimising them for the tropical climate.

3. PORTUGUESE AND ANGOLAN HOUSING STOCK IN DEMOCRATIC AND INDEPENDENCE TIMES

On April 25, 1974, the Carnation Revolution in Portugal led to the overthrow of the Estado Novo regime, significantly impacting housing policy. Interestingly, one of the critical moments of the fall of Fascimo took place in the Quinta do Morgado neighbourhood on 11 March 1975. Post-revolution, the SAAL (*Serviço de Apoio Ambulatório Local*) program was initiated in Portugal to provide housing for marginalised populations through collaboration among various parties. However, the program ended prematurely in 1976, halting housing development progress.

Following Angola's independence in 1975, international cooperation, particularly from Yugoslavia, Cuba, and Sweden, significantly influenced the post-colonial housing development. Yugoslavia's prefabrication technology, the IMS Žeželj system, was adopted by Angola, leading to the development of sustainable housing complexes in Luanda, such as the *Urbanisation*

of Lixeira, designed by Ivan Petrović leveraging existing prefabrication IMS Žeželj factories in Luanda.[17] This project featured European-style prefabricated buildings with climate-adaptive elements like loggias and balconies, contrasting sharply with the surrounding areas and showcasing the success of international cooperation in post-colonial Angola.

Cuba's international cooperation also heavily influenced Angola's housing development, creating "Cuban Blocks" in Luanda to address housing needs for civil servants. Drawing from the "Great Soviet Panel" factory experience in Cuba, the "Sandino" System emerged in Luanda like the construction systems in Havana, such as in the *Camilo Cienfuegos* and *Alamar neighbourhoods*, implemented with the same constructive system and similar architectural approaches. The transfer of the "tropical panel" spread in Cuba, as identified by Alonso and Palmarola[18], was adopted in Luanda to achieve more sustainable façades, quickly becoming a model solution to housing problems throughout the country. The first attempt was made to use lightweight, prefabricated construction elements to apply a system previously adopted by Cuba, which, when applied in Luanda without any modifications, initially resulted in a fiasco. The extremely simple modular system, of the "Sandino" type, which could be assembled without special equipment, consisting of un-insulated prefabricated concrete slabs inserted into the vertical grooves of equally pre-fabricated concrete posts spaced 1.04 metres apart, did not take into account the special socio-cultural patterns of the Angolan

people[19],This system was neither designed nor adapted to cultural or climatic requirements, but simply technically adjusted, and failed to gain acceptance in Angola. However, the introduction of technological approaches in terms of partial prefabrication became a reality with the aim of simplifying housing construction and developing production methods for heavy prefabricated parts.

By the late 1970s, Angola had adapted these prefabricated technologies to its socio-cultural and climatic context through public high-rise constructions of Cuban 5-storey buildings made of light, partially prefabricated elements. From this model, called E-14, and its successor E-15, several housing complexes, known as "Cuban Blocks", were constructed with Cuban assistance in cities like Luanda, Sumbe, and Benguela, particularly in peripheral zones. The " Cuban Blocks" in Luanda's Caputo neighbourhood consisted of 96 blocks of flats arranged in an orthogonal grid pattern. In the Cazenda neighbourhood, two smaller blocks stand adjacent to the airport, where the "Cuban Blocks" prominently feature in the urban landscape, contrasting with the only three modern blocks constructed according to Simões de Carvalho's Housing Unit No. 3. This juxtaposition highlights the shift from Luso-Angolan prefabrication at the end of colonialism to the systematisation of the Soviet System in the late 1970s and onwards.

The buildings followed the Soviet models, featured two symmetrical dwellings per floor with standard amenities like living rooms, bedrooms, bathrooms, and utility rooms. The construction of these Cuban blocks showcased a shift from Luso-Angolan to Soviet-inspired prefabrication methods, marking a new era of urban transformation in Angola post-colonialism. These projects aimed to address the housing challenges in Angola and led to the standardisation of construction practices and innovative urban forms in the country. Various architectural styles were implemented, but all shared the common goal of providing adequate housing solutions in Angola's evolving urban landscape.

4. CONCLUSIONS

The research conducted in this paper sheds light on the significant role of prefabrication in shaping housing development in Portugal and Angola during critical periods of colonial transition and post-independence. Through a comparative analysis of housing estates in Lisbon and Luanda, we've explored how the introduction of prefabricated design elements has led to functional and aesthetic innovations. In both contexts, prefabrication emerged as a response to pressing housing shortages and the imperative to provide affordable housing quickly. Large construction companies were pivotal in driving innovation, collaborating with foreign partners to introduce advanced prefabrication methods. In Portugal, partnerships with French and Swedish companies led to the adoption of innovative techniques, while in Angola, collaboration with Yugoslavia and Cuba brought in prefabricated systems tailored to local climatic conditions.

Transferring knowledge and know-how from foreign sources was crucial in these developments. Portuguese architects and engineers collaborated

19. O. Greger, "Shelter Policies and Strategies for Housing and Human Settlements in the People's republic of Angola – the first decade", 1986, DW De-velopment Workshop, https://dw.angonet.org/?s=Greger.

closely with their international counterparts, adapting prefabrication techniques to suit local contexts. This transfer of expertise facilitated the adoption of functional and aesthetic innovations and promoted cross-cultural exchange and collaboration. Furthermore, the utilization of prefabricated systems in the Global South, particularly in Angola, highlights the adaptability of these techniques to diverse socio-political and climatic conditions. From the introduction of the Fiorio system in Portugal to the widespread adoption of Cuban and Yugoslavian prefabrication methods in Angola through the variation of the "Sandino" system. These systems have transformed architectural design and urban planning, contributing to the modernization of housing stock in both regions.

The developments in Lisbon and Luanda showcased the versatility and adaptability of prefabricated systems in diverse urban contexts, undergoing numerous adaptations and upgrades to meet site-specific demands. Through partnerships between local and foreign companies, technical expertise was leveraged to shape new lifestyles amidst chaotic urban contexts. These innovations exemplify the transposition of technology during the colonial transition period, reflecting a broader trend of international exchange and innovation in architectural practices.

In conclusion, the study underscores the enduring legacy of prefabrication in shaping architectural narratives and urban landscapes during periods of colonial transition and post-independence. By exploring the interplay between prefabrication, foreign expertise, and local adaptation, this research offers critical insights into the dynamics of architectural innovation and globalization in mass housing construction.

While this study sheds light on prefabrication's role in housing development in Portugal and Angola, future research could explore its long-term impacts on housing quality, durability, and sustainability. Longitudinal studies tracking prefabricated buildings' performance over time could provide valuable insights into their effectiveness and areas for improvement. Additionally, investigating the social and cultural dimensions of prefabricated housing could uncover how these systems influence community formation, social cohesion, and cultural identity. Comparative studies across other regions of the Global South could offer insights into prefabrication's transferability across different contexts and climates.

Overall, by building on the findings of this study and addressing these research gaps, scholars can continue to advance our understanding of the role of prefabrication in shaping the built environment and addressing the challenges of housing provision in diverse socio-cultural contexts. ■

THE ROLE OF PREFABRICATION IN HOUSING CONSTRUCTION IN THE 1970S IN CHINA: THE CASE OF DIPLOMATIC RESIDENTIAL COMPOUNDS IN BEIJING

YIMEI ZHANG
TECHNICAL UNIVERSITY OF MUNICH

ABSTRACT.

Collective housing built after the founding of the People's Republic in 1949 and prior to the commercialisation of the housing market in 1998 is an emerging research field in China. However, existing scholarly attention is paid to housing projects from the 50s, which were built under Soviet influence and are now officially recognised as heritage. The technology of prefabrication in housing construction in China remains underexplored.

The paper argues the 70s was a crucial period in the research of prefabrication in China, and the case of Diplomatic Residential Compounds (DRC) in Beijing provides important clues. Constructed in 1973, DRC was the first high-rise residential building in the capital city, and also one of the first to fully use prefabricated components in high-rise residential buildings.

The paper illustrates the development of prefabrication technology in housing construction in China, examines how this technology was tailored to accommodate the needs and available resources, and concludes that despite the consistent effort, the prefabricated panel system was not as widely applied in China as in other countries due to the limited capacity of industrial production.

1. INTRODUCTION

In the early 1970s, though internally still deeply entrenched in the Cultural Revolution, China achieved great diplomatic breakthroughs on the global stage. Between 1970 and 1972, diplomatic ties with 36 nations were established, marking China's integration into the international community. This momentum was catalysed by its admission to the United Nations in 1971, and landmark visits by then-US President Richard Nixon and Japanese Prime Minister Kakuei Tanaka the subsequent year.

Several buildings assigned for diplomatic purposes were built to accommodate the growing demand of foreign embassies and visitors. Most of these constructions were situated in the designated "diplomatic district," which was established in 1957 on the east side of Chang'an Road, in an area measuring 60 hectares. One such building was the Diplomatic Residential Compound (DRC), constructed in 1973 to house diplomats. The compound is comprised of two sixteen-storey, two six-storey and one four-storey residential buildings in an area of 20,300 square metres. It was the first high-rise residential building in the capital city, and also one of the first to use prefabrication methods in high-rise housing.[1]

The two high-rises in the compound were undoubtedly an architectural marvel in the 1970s in the capital city. The two sixteen-storey towers on the central east-west axis of Beijing showcased the construction achievement of the young nation. After their completion, they quickly became a modern landmark appearing on postcards and calendars. Their architectural experiment also made the cover of the *Architectural Journal* in 1974, one of the oldest and still the most influential academic journal in the field in China.

However, the DRC appears to have somewhat faded from the spotlight of architectural history. While it receives brief mentions in various publications, a comprehensive exploration of its design and construction within a historical context is lacking. In the list of China's 20th Century Architectural Heritage, published since 2014 which has included 900 sites, the DRC was absent, despite the fact that another diplomatic residence next to it and built 3 years later was included in 2019.[2] The oversight of the DRC raises questions about the significance of prefabricated concrete panel systems in China's housing development history and why their contribution remains overlooked. This discrepancy underscores the need for further investigation into the role of prefabrication in shaping China's architectural landscape.

2. DESIGN

At first glance, there is a parallel in housing development between China and countries under the Soviet influence after the Second World War. Following its independence in 1949, China adopted the Soviet model in various aspects of society, including housing construction and design. Inspired by Nikita Khrushev's speech in 1954 on the industrialisation of housing construction, China's State Council issued the Decision on Strengthening and Developing the Construction Industry two years later. This document emphasised the standardisation of design, industrial production of construction material and

2. The list is published under the guidance of the Chinese Society of Cultural Heritage and the Architectural Society of China. It is an advocacy and awareness-raising list, not an official designation of heritage, though some sites on the list are already designated.

the mechanisation of the construction process.[3] Following the Soviet model, in 1956, the Institute of Standardised Design was established, and a year later, a catalogue of standardised design for housing was published. The designs considered seven different regions and four levels.[4]

In 1956, the first standardised housing design in Beijing was developed with the help of a Soviet expert, known as Type II design. The floor plan adopts the Soviet standard of 9 square metres per capita living area, and bears resemblance to the K-7 Series in the Soviet Union. In an effort to achieve maximum standardisation, only one room size —3.2 metres by 6 metres— was used. However, the Type II Design was not yet built with a high level of prefabrication. On-site casting of concrete floor panels, brick load-bearing walls and wooden roof trusses were typical in the 1950s as the major construction method.[5]

The parallel development with the Soviet system only lasted for a short period in the 1950s, not only due to the divergence of politics which finally led to the Sino-Soviet split in 1958, but more importantly, due to the lack of required industrial infrastructure and technology. Although the system adapted from the Soviet Union largely remained until the commercialisation of the housing market in the 1990s, it did not result in the dominance of one or several standardised designs. In fact, China had been struggling between standardised design and local reality throughout the decades. Despite being well-informed about global housing developments through translated literature and delegations sent overseas, China faced challenges of adapting designs and technologies to its own circumstances.[6] During the late 1950s and the 1960s, ideologically-driven policies led to a continuous downward adjustment of design and construction standards. For instance, in 1957, the Type II floor plan was deemed excessive for China, prompting the National Commission of Planned Economy to issue regulations limiting the maximum living area per household to 18 square metres and an average of 4 square metres per capita living area.[7]

The DRC appears to be one of the first carefully designed residential buildings in a decade. Eighteen plans were made for the site, out of which a plan that combines towers and low-rises was chosen.[8] The two six-storey and one four-storey low-rises were built using a conventional brick and concrete structure, which utilises brick for vertical load-bearing walls and reinforced concrete for structural columns, beams, and floor slabs. The design of the tower was also chosen among a handful of drafts, including a Y-shape plan, resembling the P2 Type in Dessau, developed in 1971 in the German Democratic Republic. However, the plan was eventually abandoned due to its complexity and the difficulty in standardising building components. The final double-rectangle plan struck a balance between a varied streetscape and ensuring the feasibility of construction.

A lot of the design considerations in the DRC[9] were reflected in the standardised design in the 1970s in Beijing, which signals a departure from the previous policy which emphasised solely cost-effectiveness and minimal standards. A pivotal moment was the issue of the Revision of Residential

Building Standards by the State Construction Committee in 1973, which allowed for the average residential floor area per household to be 34 to 37 square metres, doubling the standard in the 1960s, and permitted more spacious and comfortable housing designs. A prominent feature is the enlargement of the narrow entrance corridor into a small lobby area, which is not only a notable feature in the DRC, but also in the 1974 standardised design. Beginning in 1970, the task of standardised design was also decentralised to local levels, giving rise to more diverse floor plans in different regions.

The DRC's distinction from other residential buildings is also notable. Unlike the prevalent scale of 2.7, 3.0 and 3.3 metres in standardised floor plans since the 1950s, the DRC adopted larger 4 and 5-metre scales, with designated spaces for reading, dining, and service rooms. The same scale was also used in another diplomatic residence building constructed three years later. This departure from the norm reflects the effort to align with international standards of living.

3. TECHNOLOGY

Constructing DRC with fully prefabricated component was a deliberate choice. The prefabricated concrete panel system was not a new concept in China during the 1970s. It had already introduced in the 1950s during the first Five-Year Plan Era (1953-1958), when Soviet experts provided essential technical support for the so-called "156 major projects" of industrial development. Low-rise housing complexes using prefabricated concrete panel systems were first built in the Northeast region, using the technology developed by Soviet engineer, Vitaly Lagutenko. The panel was very thin, with ribs on all four sides to bear weight. In 1959, the first experimental building using Lagutenko panels was built in Beijing, in the neighbourhood of Muxiyuan.[10] Despite the political standstill after 1958, Soviet experts continued to provide key instructions in the experiment building.[11] The panel used was 3.6 metres wide and 5.4 metres long, 5 centimetres thick, with ribs on the edges to bear load from all four directions. Concrete blocks of 13 centimetres thick mixed with ground granulated blast-furnace slag were used as insulation layers of the panel.[12]

From the late 1950s through to the 1970s, prefabricated panels changed very little. In the experimental housing built in 1963 in Beijing Shuizhuizi, variations of Lagutenko panels continued to be used. The concrete panels were 4 centimetres thick, filled with 16-20 centimetres of slag mix insulation.[13] The experimental building was quite successful, but the construction cost was allegedly 1/4 higher than traditional construction, which led to doubts about the wider application of this technology.[14] Efforts to lower construction costs also led to experimenting various mix materials to reduce concrete consumption. Ground granulated blast-furnace slag and expanded perlite emerged as a popular material for concrete mix.[15]

In the 1970s, the panel system had not significantly advanced beyond the Lagutenko prototype. When constructing the sixteen-storey DRC tower, several technological solutions were considered. Cast-in-place concrete

and steel frame structures, although prevalent in many high-rise buildings at the time, were deemed too costly for residential construction and were consequently ruled out. The load-bearing prefabricated concrete panel system, widely employed in the Soviet Union, East Germany, and other countries during that era, had not been experimented with in China. As a result, the final solution is a combination of reinforced concrete frame as the load-bearing system and thin concrete wall panels. The panels were 1.5-centimetre-thick with two sets of ribs on all four sides and a prestressed steel frame embedded. A layer of 12.5-centimetre autoclaved aerated concrete was added for insulation. All the components were prefabricated in factories and assembled on-site.[16]

Due to a decade of technological stagnation, the construction method for the tower block had to be developed from the ground up. The structural integrity and seismic performance were first tested with a three-storey experimental building.[17] The Beijing First Architecture Construction Company, tasked with manufacturing the panels, established two new production lines specifically for this project with no prior experience. Despite the challenges, prefabrication was proved to be an efficient industrialised construction method. The record speed of assembling one storey was 4.39 days.[18]

4. COMPETING SYSTEMS

Following the successful completion of the DRC, the prefabricated concrete panel system gained momentum in housing construction. In 1974, two eleven-storey residential buildings using load-bearing prefabricated panel system were built in Beijing on Tiantannan Road. The concrete panel is 13 centimetre thick with a layer of 12.5-centimetre autoclaved aerated concrete insulation.[19] While the technology may not have been considered groundbreaking by international standards, it nonetheless represented a significant breakthrough in housing development in China, and was awarded the National Science Award in 1978.[20] In the same year, the National Architecture Committee published the Interim Provisions for Structural Design and Construction of Assembled Large Panel Residential Buildings.

The cast-in-place concrete system was developed in the early 1970s and has become a major competitor with the prefabricated panel system. It was also awarded the National Science Award in 1978.[21] By 1980, the total area using the cast-in-place concrete system was double the area of prefabricated concrete panels, despite the application of prefabricated panel system was also growing quickly.

Several factors have contributed to the wider application of the cast-in-place concrete system. However, the production, transportation and assembly of concrete panels still posed technological challenges. By the end of 1980, only 28% of residential buildings were using industrialized construction methods, out of which only 6.35% used the prefabricated panel system.[22] The concern for seismic performance also loomed large as the 1976 Tangshan earthquake, one of the most tragic natural disasters in contemporary history in China, led to a higher requirement for earthquake resistance. Structural stability was a recurring discussion for prefabricated panel systems in the late 1970s and the 1980s. The constant variation of standardised design was also mentioned as a major impediment to the large panel system. The decentralisation of standardised design in the 1970s and the growing need for better, larger and more diverse living spaces gave rise to systems that were more adaptable to local needs.

5. CONCLUSION

The technology of prefabrication was introduced to China in the 1950s with Soviet technological support and did not advance much in the following decades. The 1970s witnessed a breakthrough of prefabrication in housing construction in China. Despite being valued for its high level of industrialization and construction efficiency, this technology was not widely applied in China compared to other countries due to technological restraints. ■

EXPORTING SOVIET MONUMENTAL ART FROM SOVIET TASHKENT TO EUROPE AND SIBERIA: THE WORKS OF ALEXANDER, NIKOLAI AND PYOTR JARSKY BETWEEN 1969 AND 1999

PHILIPP MEUSER
MEUSER ARCHITEKTEN GMBH/DOM PUBLISHERS

ABSTRACT

This paper aims to shed light on the remarkable oeuvre of the Jarsky brothers, showcasing the best examples of their projects. The facades they designed serve as a bridge between art and architecture, as the brothers developed a method to integrate mosaics and reliefs into precast concrete panels. Despite the industrial and highly standardised construction methods and political control, they managed to preserve their individual artistic freedom and evolve creatively. Their work combines floral ornaments and programmatic motifs, linking the heritage of Islamic architecture with the functionalism of Soviet construction. The initial phase of their work features traditional Uzbek ornaments found on historical buildings, while the motifs from the mid-1970s increasingly incorporate political content. Many facades depict representations from space exploration, mathematics, and natural sciences, combined with idealisations of the Soviet citizen. Only in the 1980s did the trio embrace a more abstract and artistically free vocabulary of forms.

The Tashkent Modernism movement has recently brought renewed attention to Soviet architecture in the capital of Uzbekistan. Within this context, the Jarsky brothers' mosaic facades on panel buildings stand out as exceptional examples of artistic expression amidst the often-perceived monotony of Soviet Union typology. Pyotr, Nikolai, and Alexander Jarsky designed colourful mosaic images and expressive reliefs for over 200 buildings in Uzbekistan, primarily in the capital city of Tashkent. Among other cities, the Jarsky had worked in Dushanbe/Tajikistan, Tbilisi/Georgia **(Fig. 01)**, Chisinau/Moldova **(Fig. 02)**, Vladikavkaz/North Ossetia, and Nyagan/Siberia. Despite being the most extraordinary examples of Soviet mass housing, part of the world's most extensive housing program since the early 1970s, the Jarsky brothers' work remains relatively unknown internationally. However, that will change shortly. On 25 March 2024, the Uzbek government placed 157 façade mosaics under special protection. Since then, property owners have only been able to hang a billboard over the façades or carry out modernisation or renovation measures following an approval process.[1] The extent to which individual mosaics were selected on residential buildings from the Soviet modernist period will also be included on the UNESCO World Heritage List and will remain to be seen shortly.

#09

Industrially prefabricated standardised buildings have always triggered controversial discussions in architecture. Especially during the reconstruction of destroyed cities in Europe after 1945, architects and engineers debated the lack of design standards on the one hand and the potential for structural optimisation on the other – spurred on by a housing policy that wanted to build "faster, better and cheaper". This applied to both the Western world and the socialist world. Three generations of architects later, we are once again discussing the possibilities of meeting the housing shortage by planning standardised buildings and saving costs in the process.

The debate on typified architecture has received new impetus in recent years. The academic reappraisal of late modernism, also known as Eastern modernism ("Ostmoderne") or Soviet modernism in the former socialist context, has enriched the circles of architects, art historians and critics with aspects of the monumental value of industrially prefabricated buildings. This raises the question of what value an individual building has if the construction industry has erected it dozens or even hundreds of times in a similar form. We discuss whether, for example, the prototype, its variant, or the significant urban location of such a building are reasons for its preservation.

These questions are understandable in the context of the German housing debate. We live in a state of abundance and unequal distribution. We are still building back empty residential buildings in shrinking regions while living space in urban centres has become a scarce commodity. However, how is such a discussion perceived in economically less prosperous regions? Is it not presumptuous to point the finger from a Western perspective and call for a different or even absent understanding of monument protection?

Anyone who has seen the mosaic art on the more than 200 prefabricated building façades in Tashkent may not immediately consider the question

of monuments. However, this question must be asked! While authoritarian states such as Uzbekistan presume to allow only one valid historiography and merely use pre-modern architecture as a backdrop for official identification, external impulses are needed. Such a sharpening of awareness can contribute to recognising one's architectural values and utilising these not only academically and politically but also for tourism and economic purposes. Three approaches can be pursued in the case of mass housing construction in Tashkent after the 1966 earthquake. These points are incomplete and should be critically scrutinised and completed by young academics in Uzbekistan.[2]

1. THE MONUMENTAL VALUE OF INDUSTRIALISED TYPE BUILDINGS

Industrialised type buildings represent an innovative and standardised approach to architecture. While some argue that standardisation reduces the individual value of the buildings, the possibility of shaping an architectural style through the repeatability of the buildings is also emphasised. This is particularly true of Soviet housing construction. The significance of the first realised house in a type series can be seen as the starting point for developing a typological design language. Identifying these prototypes or pilot projects is a first step.

2. URBAN CONSERVATION

Another aspect of the monumental value lies in the urban significance of the type buildings. If a specific type of building characterises the cityscape and significantly contributes to the urban environment, monument protection on an urban planning scale can be considered. This approach requires a more detailed analysis of the impact and significance of the buildings in the context of the social life of their inhabitants. In the case of Tashkent, the conversion to a model Soviet city can be traced through the residential areas, which had to make way for neighbourhoods of single-storey mud houses.

3. THE MONUMENTAL VALUE OF THE JARSKY BROTHERS' FAÇADE ART

The unique case emphasised in this paper is the monumental value of the façade mosaics by the Jarsky brothers in Uzbekistan and other former republics of the USSR. Over the past twenty years, a new academic discourse has developed that identifies and documents the qualities of Soviet modernism – including architectural art – and stimulates discussion about its preservation. This example illustrates the need to consider and evaluate the monumental value of such forms of expression in different cultural contexts.

Prefabricated housing was a global and cross-cultural phenomenon that defined the architecture of the twentieth century. No other architectural endeavour has significantly influenced people's daily lives – their sense of freedom within their four walls. It is still too early to assess whether this struggle for affordable homes and social equality was a failure or a success. When the reconstruction of Europe's war-torn cities began in the 1950s,

2. Philipp Meuser, *Fassadenkunst im Plattenbau. Das Werk der Brüder Jarsky im sowjetischen Taschkent* (Berlin: DOM publishers, 2023).

planning and construction quickly became part of a political agenda that promised hope, happiness, and progress. Broad government support, both in the East and the West, enabled mass housing to flourish, providing many families with an affordable home in a short period. The ideological conflict during the Cold War inspired a flurry of capitalist and socialist strategies for solving the housing problem.

The success story of standardised mass housing in the Soviet Union begins in the mid-1950s. Nikita Khrushchev, introduced a radical change in planning and construction. Millions of prisoners, released from labour camps by decree of Khrushchev, were flocking to the cities and searching for a home, which placed even greater pressure on the already strained housing market. The form of standardised mass housing, bearing the name Khrushchyovka, changed the face of Soviet cities. For the first time, these new buildings introduced an urban – albeit monotonous – quality to many settlements in Siberia, the Eurasian Steppe, and the Far East.

By its dissolution in 1991, prefabricated housing accounted for up to 75 per cent of all homes in the Soviet Union.[3] The rest of the homes comprised conventional brick buildings built mainly according to standard designs. In Tashkent, the capital of the Uzbek Soviet Socialist Republic (SSR), the share of prefabricated housing rose to 75 per cent by the early 1990s, with a total floor area of between 3.1 and 3.5 million square metres. These numbers also typified other socialist states, such as the GDR, where prefabricated buildings accounted for 75% of all housing. The construction of new homes dropped by almost 50 per cent in terms of floor area between 1991 and 1995.

4. ARCHITECTURAL LABORATORY ON THE SILK ROAD

Tashkent exemplifies Soviet architecture while boasting distinctly regional features. After the earthquake of 1966 destroyed most of its historic centre, it became the site of an all-union reconstruction effort. Republics across the Soviet Union sent workers to rebuild the city following a pre-approved master plan **(Fig. 03)**. Soviet propaganda organs seized on the event as a demonstration of the so-called friendship of the peoples, which shows the importance of architecture, space travel, and military technology in the Soviet people's imagination. However, while the city of Tashkent was built in accordance with a markedly Soviet architectural style, it contains a wealth of regional ornamentation unmatched by any other republic of the USSR.

The brothers Pyotr Jarsky (1929–1993), Nikolai Jarsky (1931–2014), and Alexander Jarsky (1936–2015) created an array of remarkable artworks for buildings in Tashkent. Thanks to them, the city boasts over 200 façades with colourful mosaics and filigree reliefs. The floral patterns and programmatic motifs combine the heritage of Islamic architecture with Soviet modernism's euphoric anticipation of the future. The Jarsky brothers arrived in Tashkent shortly after the earthquake of 1966, seeking to introduce their ideas on façade design. 'The best place to create something new, beautiful, and useful is where much is being built. At the time, Tashkent was such a city.'[4]

3. V. A. Kossakovsky and V. A. Chistova, *Architectural Compositions of Residential Buildings* (Moscow, 1990).

4. Quote of Nikolai Jarsky in *Vecherny Tashkent*, February 12, 1972.

The Jarsky brothers' first building-height decorative mural adorned a nine-storey residential building on Mukimi ko'chasi in the district of Chilonzor. Many years later, the architect Jury Miroshnichenko made the following comment on this design, created by the eldest brother Pyotr: 'This design bewildered the architects. Its composition, colour, and subject matter did not reflect the Uzbek people's popular ideas on ornamentation. The red, brown, and golden hues, the sheer size, the composition's boldness, and the creators' imaginative power did not immediately speak to us. Only the unmistakable talent of the painters made it clear that the design needed to be realised. An analysis of the first mural revealed that it drew on many elements of Uzbekistan's cultural heritage. The work was closer to the ancient art of Afrasiyab and Panjakent than to creations from later periods, which typically display a more intricate ornamental style. The use of ancient, forgotten stylistic and compositional traditions conferred on this work a special value and made it stand out among modernist artworks.'[5]

Although the author's comments refer to the artwork rather than the architecture, such high praise is rare for a standardised, prefabricated residential building in the literature on Soviet housing. As such, the works of the Jarsky brothers can be seen as unique, both quantitatively and qualitatively, in the history of Soviet architecture. It becomes clear that Tashkent attempted to introduce variety to the monotonous panel-building façades through ornamentation, reliefs, and varying arrangements of façade elements.

Nikolai Jarsky, who was the head architect of the DSK-2 housing combine from 1972 to 1991, not only designed mosaics but also reliefs for balcony parapets and sun-protection elements in front of loggias. These elements had an enormous influence on the cityscape, which prompted Jarsky's employee Miroshnichenko to claim euphorically: 'A group led by head architect Jarsky and head engineer Prassolov has been working for several years on a new kind of relief that can be used for multi-storey façades. Unlike smaller ones developed in previous years, this relief has been met with great approval. Since then, a design team at the housing combine has been tirelessly planning the prefabrication of the relief. It has already brought greater variety to the city's buildings, and each district has taken on its architectural appearance. Today, we can speak of a unique Tashkent style!'[6]

5. BETWEEN INDUSTRIAL PRODUCTION AND ARCHITECTURAL CRAFTSMANSHIP

A builders' newspaper based in Tashkent published several articles praising the works of the Jarsky brothers. An article in 1973 reported that in the past, only artists had created mosaics as part of a costly process. Now, three architects, the Jarsky brothers, were designing all mosaic murals directly at the DSK-1 housing combine, taking care of all tasks, from selecting the motifs to the moulding. 'The techniques for producing mosaic panels have been improved and simplified. Pyotr, Alexander, and Nikolai Jarsky draw a full-size pattern on paper. Mosaic setters then paint colourful tiles onto the drawing, and the finished template is laid into a mould. After the concrete

is poured into the mould, the paper is removed, and the tile pattern remains fixed on the panel. The completed panels are delivered to the construction site and assembled. The Jarsky brothers constantly seek new ways of improving production techniques and reducing costs while searching for unique images and patterns. The architects have also introduced the use of broken tile fragments, which were previously thrown away but are now used to create finer decorative patterns. This way, the housing combine has saved on costs without affecting the quality or beauty of the ornamentation.'[7]

The fact that a daily newspaper published an article praising a detailed building process highlights the significance of housing in the USSR. In Tashkent, where the Jarsky brothers created most of their work, art for architecture also drew particular attention because the reconstruction of the city after the earthquake of 1966 had become a defining feature of the Uzbek SSR capital. So, it was only natural that a news report should cover the construction of the first experimental prefabricated residential buildings. In 1970, the Tashkent evening newspaper published a feature on a new job in the construction industry: 'Two of the Jarsky brothers, Alexander and Nikolai, left their positions at a planning institute ... in order to produce their monumental art at an urban scale and create a more beautiful cityscape. A new profession has also emerged in the building industry, with the opening of a new office at the DSK-2: that of the mosaic tile setter.' The article continues with a description of the work process: 'A large piece of paper hangs on the wall with a black-and-white drawing: a figure of the Madonna, between exotic flowers and plants, holding the sun in her hands. It is the sketch of a future mosaic mural that will adorn a residential building in Tashkent. There are many such sketches at the workshop. Some can already be seen and admired on façades in the city; others are still being prepared. We spoke to three tile mosaic tile setters on the day of our visit: Lyuda Byelichenko, Nina Kuzmina, and Natasha Paramonova. They were busy putting together a pattern for a gable façade. They glued small, colourful tiles onto a piece of paper lying on the floor, one tile after the other. We could already recognise a green leaf or a beautiful flower. One thousand five hundred tiles and fragments were laid on a surface measuring two square metres. The women told us the three require around 20 work days for a 150 square-meter mural.[8]

The Jarsky brothers' success could not have been foreseen in the Soviet building industry. However, neither the factory management nor the party leadership objected to the decorations since the work of the predominantly female tile setters was incorporated into the production process for the large panels, and the motifs could be created directly at the factory. The Jarsky method was exceptional because the mosaics and the load-bearing panels were cast together as a single unit at the factory. Although the approval authority GlavAPU had the final say in the choice of images, the Jarsky brothers at least had the right to make suggestions. The influence of politics on the design of the façades and the construction process as a whole sometimes came from the highest level. 'Sharof Rashidovich Rashidov, at the time the First Secretary of the Communist Party of Uzbekistan, examined

7. 'Rivals of the Old Masters', in *Stroitel Tashkenta*, February 7, 1973.

8. 'Where Beauty Is Created', in *Vecherny Tashkent*, October 31, 1970.

the decorated panels at the housing combine and approved their assembly on the construction site.'[9]

6. THE JARSKY METHOD: TO GIVE ANONYMOUS BUILDINGS AN INDIVIDUAL FACE

Although secular buildings in other parts of the USSR have remained anonymous, in Tashkent, the expressive mosaics and reliefs on the gable façades of nine-storey residential buildings are linked to Alexander, Pyotr, and Nikolai Jarsky. Within three decades, the artist trio created over 200 façade designs that define the cityscape and testify to a search for a national style. Remarkably, the individually designed façade decorations were used not only to adorn prestigious residential buildings for the Nomenklatura and public buildings strategically placed at prominent locations in the city but also prefabricated mass housing series. The motifs range from oriental patterns to figurative representations through to geometric forms. Most of the façade mosaics hang on the front side of nine-storey residential buildings of Series 1-TSP, which were produced at the DSK-2 housing combine. Nikolai Jarsky said the challenge was to 'break the monotony of the prefabricated mass housing series, each time with a new image.'[10]

Four experimental housing projects realised shortly after the earthquake show that architecture in the Soviet Orient increasingly took on a national character. The projects include large-scale ensembles and several smaller individual buildings, some of which feature mosaic façades by the Jarsky brothers. For the housing development along Ulitsa Bogdana Khmelnitskogo (today Babur ko'chasi), Pyotr Jarsky created a building-height mosaic relief depicting a portrait of the Uzbek national hero Zahir ud-din Muhammad Babur. The building, which contains 500 apartments, also features a natural ventilation system that functions like a heat exchanger.

While Nikolai and Pyotr Jarsky worked in Tashkent from 1969 into the 1990s, the youngest brother, Alexander, left the city to travel extensively for almost ten years. He worked in various places in the Caucasus and Udmurtia, where he and his family settled after emigrating from France in 1947. In 1980, he created a façade mosaic in Izhevsk using the technique developed in Tashkent – by casting the mosaic tiles and the concrete for the wall panels together as a single unit. However, the two brothers who remained in Tashkent also worked outside Uzbekistan, designing façades for Kulob in Tajikistan and Tbilisi in Georgia. However, Tashkent remains the city with the most incredible variety of colourful façades in Soviet mass housing. It remains the city with the world's most beautifully decorated panel buildings. ■

RESHUFFLING URBAN LAND: MODERN IDEAS FOR NEW URBAN MORPHOLOGIES

FRANCISCO DÍAZ
PONTIFICIA UNIVERSIDAD CATÓLICA DE CHILE

MARCO TRISCIUOGLIO
POLITECNICO DI TORINO

ABSTRACT

Well-known for their utopian character, many modern urban proposals never found a fertile ground. Criticized for breaking the city fabric and sometimes even considered antiurban, the city projects developed by the first wave of modern architects were treated as the unpleasant other of well-received architectural designs.

However, one aspect of these projects is usually overlooked: replacing the old urban fabric implies a total reorganization of land property schemes. In fact, if we look at the urban morphology in terms of property, we will see that the city fabric is nothing but a stubborn crystallization in time of land property regimes. Thus, the continuity of the urban fabric is, in fact, a continuity of land property schemes that, in the end, are an endless source of surplus value—and hence, one of the main reasons for economic inequality.

World War II and the rise of Urban Renewal schemes gave a new boost to these modern ideas. Within this scenario, a second wave of modern city projects was developed, one which aimed at overcoming the shortcomings of the first wave. In the few cases in which these ideas touched the ground, they dealt with preexisting property regimes, reshuffling them to generate a new urban fabric and, thus, a different way of designing the city.

Through a discussion of the nature of the public and private debate on the city, "Reshuffling urban land" aims to see how the ideas of modern architecture went into the core of economic inequalities by reshuffling land property regimes to generate a different city. In the end, we want to know whether we can still think of a new form of city—one where land property is no longer the main defining factor.

1. INTRODUCTION

Widely quoted as an example of contempt for the past and the awful urban ideas of modern architects, 1925 Le Corbusier's Plan Voisin found a new interpretation in Víctor Velásquez's research. Analyzing in depth a colored general plan of the project published in 1926, the Colombian scholar realizes that "The use of color in the floor plan helps to distinguish the new buildings (in black) from the large green zones gained by the city. Additionally, the red indicates the patrimonial buildings that the Voisin Plan maintains" (Velásquez, 2016:234). By redrawing the plan and geolocating its elements, he discovered that the red buildings were historical landmarks of Paris that Corbusier chose to keep. Thus, it was not true that the Swiss-French architect wanted to destroy Paris completely. He only wanted to eliminate the urban fabric that Caniggia (2018) would have called "basic buildings" while keeping the remarkable ones. Although this selective removal of the urban fabric could be understood as a reaction to Camillo Sitte's proposals, it was not a novel idea. By preserving those buildings we would now consider as heritage, Le Corbusier was not breaking with history but only choosing one tradition over another. This could lead us to think Le Corbusier was not as progressive as many would have thought. However, since tabula rasa was to be applied over the unremarkable constructions and narrow, medieval streets, the real change would happen in the urban fabric and, hence, in the relationship between buildings and urban land.

Although the apparent radicality of tearing down a significant part of Paris' city center may have seemed utopian, or a theoretical construct, the need to rebuild large urban areas destroyed during WWII opened the chance to test modern urban models like those that Le Corbusier proposed twenty years before. Yet, by then, a new generation of architects had taken the baton and the Swiss-French architect was not called to work on these redevelopments. In 1951, the VIII CIAM held in Hoddedson, England, under the direction of Josep Lluis Sert, worked around the idea of "The Heart of the City", and the need to rebuild those blasted city centers could have brought Plan Voisin back to the discussion. However, the discourse was already shifting, and the question was no longer for radical tabula rasa schemes but rather for more conservative approaches that could help recover the sense of community lost during the war (Mumford, 2000). The so-called "Corbusians" (Mumford, 2018:227) lost the conceptual battle, and more nuanced approaches to the reconstruction of city centers began to be promoted.

In order to offer a new lens to read this well-known historical debate, a question needs to be answered: What is 'the heart' of the city? And why would the city need a heart in the first place? In animal bodies, the heart is the organ that propels blood to the arteries, carrying nutrients and oxygen. The heart is the engine of vitality. In the biological analogy of the city, a heart that pumps vitality to the 'arteries' (a term widely used as a synonym for 'streets') is that which renews the flow of what makes the city alive. The movement of people through the streets becomes analogous to blood running through the veins. However, since the city's arteries are not tubular pipes but open and

visible public spaces—streets—the flows must be publicly visible. Since in the urban realm vitality equals public life, then "the heart of the city" is that which pumps public life.

2. SOME DEBATES ON THE PUBLIC AND PRIVATE

Insofar as tabula rasa schemes turned corridor streets into roads, effectively denaturalizing the arteries that could channel public life, urban schemes like the Plan Voisin would threaten the vitality of the city. If streets were only routes for transportation, public life would be in danger. Perhaps that's why the recovery of life on the street became a central issue for architects like Allison and Peter Smithson and many of their comrades within the Team X (Smithson, 1968). And back then, this concern was not reserved only for architectural discussions. In 1958, Hannah Arendt published her seminal book The Human Condition, reopening the question of the public sphere and retracing it back to the Greek polis (Arendt, 1958). Perhaps inadvertently, this work reinforced the connection between public life and historical urban models.

In 1974, Richard Sennett's book *The Fall of the Public Man* [*sic*] continued this path. For the North American sociologist, the increase in close contact in the streets brought by bourgeois efficiency led to a decrease in sociability, turning public space into a mere place for transit between interiors (Sennett, 2002 [1974]:15). Looking at the ancient regime's cosmopolis, he observed that 'public' was the life outside the house and the family: a life lived in the streets and public spaces. In his theatrical view, people were like actors, with the city as their stage and strangers acting as the audience. This realization gives room to Sennett's idea that "a city is a human settlement in which strangers are likely to meet" (Sennett, 2002 [1974]:39). The encounter with what is strange seems a condition for public life. This is why Sennet argues that small communities cannot be the antidote against capitalist cities. On the contrary, they could become even more conservative because "the community exists only by a continual hyping-up of emotions" (Sennett, 2002 [1974]:309). For him, the only way to escape this trap would be to recover the complexity of the ancient regime's cosmopolitan city, whose public domain is full of people who don't know each other. This encounter with those who are different could help enrich the understanding of the world and make people less provincial and more open to diversity. This complexity would be the opposite of the schematism of the first CIAM's urbanism, that of the functional city and the Charter of Athens.

This idea that the public can only appear in the ancient regime has undoubtedly been confronted. Urban political scientist Alan DiGaetano argues that "The confluence of urbanization, rapid industrialization and commercialization, democratization, and nation-state consolidation in the nineteenth century provided the historical context for the creation and expansion of the public domain" (DiGaetano, 2006:456). It was the convergence of these forces that led political leaders to seek for "pragmatic ways to manage the resultant social, economic, and political dislocations by creating and expanding the local public domain" (DiGaetano, 2006:459).

In other words, the public domain—a conflation between the public sphere and modes of governance—would be the unintentional consequence of a pragmatic resolution to conflicts. Here, 'the public' is an outcome of the authorities' reaction to a demand (from the public) and not a realm of its own. It would then be a specific invention of liberal, enlightened States instead of an entity that precedes those States and gives them legitimacy. Thus, the public would be linked to the modern city rather than to an ancient or historical urban formation. But we must not conflate modern with modernist since DiGaetano's 'modern city' is the one generated by modern production conditions and not the one envisioned by modern architects.

By establishing this public/private relationship on several levels and explaining the meanings of the tandem in each one, political theorist Jeff Weintraub made a more profound and precise assessment of the dichotomies between public and private. To begin, he uses the analogy of the 'two cities:' in one, the public would be based on political participation—the 'polis'—while in the other, it would be related to the enjoyment of difference—the 'cosmopolis,' exemplified by Babylon. In both cases, the private realm would be the realm of personal life: work, discipline, and the inner world of the family. However, Weintraub sees contradictions and grey zones within each of these levels. For instance, the notion of the public as political may come either from Greece or from Rome; in the former, the model was the polis, and the public means decision-making, whereas, in the latter, it meant administration since the framework was the 'republic'—res publica. In the same vein, Weintraub argues that many times, "the distinction public/private corresponds […] to the distinction political/nonpolitical" (Weintraub, 1997:36), as if the private realm—for instance, the market—wouldn't entail political choices. The reductionist logic of this view is evident because "just as the 'public' realm (and politics) cannot be reduced to the State, the realm of social life outside the State (and its control) cannot simply be identified as 'private.'" (Weintraub, 1997:15).

From architecture, thinking with Weintraub allows us to see some territories of inquiry. For instance, he criticizes Sennett's understanding of the lost sociability as "a threatening dialectic between 'dead public space' and a pathological overinvestment in intimate life." (Weintraub, 1997:24). Since to declare a public space as dead you need a corpse—a piece of material evidence—Sennett seems to refer to the facades of the corridor street, the theatrical space of the city which was, for him, the main stage for sociability. Like a vein without blood, a dead public space would be a corridor street without vitality, a city where the intimate, private life would happen behind those facades, in the black areas of a Nolli map. But perhaps, just like the dual palette of that famous map of Rome, Sennett may have been working with a binary scheme. Thus, the grey areas are territories waiting to be explored.

Weintraub also claims that "the separation of space into work areas and living areas corresponds to the division of life into a public sector and private sector." (Weintraub, 1997:25). Here it is easy to see a reference

to the modern, functional city of the first CIAMs. Yet, as seen earlier, architectural discourses not only left that schematic view of urban functions behind long ago, but also have recently been exploring new models or recovering older ones that merge life and work, thus blurring the distinction between public and private.

Furthermore, if "the city is both an object of theoretical analysis and, simultaneously, the metaphorical source of many of the key concepts of Western social and political theory" (Weintraub, 1997:26), it seems clear that architecture has something to say in this discussion. Although architects don't design the city (at least alone), architecture's tools, methodologies of analysis, lexicon, and overall, its specific position with the structure of urban production could be helpful to a better understanding of the complex nature of the public/private relationship. While for Weintraub, the city is a privileged object to look at and a metaphor to speak about the public, in architecture, the city is much more than just a metaphor, and our tools can help understand that object better. In fact, most of the different perspectives he presents speak of spaces that include, exclude, and have convoluted relations between them—and that is precisely the territory in which architecture feels at ease.

For example, architecture can help surpass the obstacle of being too close to the object of analysis. Because if we live in cities and belong to some form of public, how can we analyze something we are part of? How can we define the contours of a space we are immersed in? In architecture, we know how to detach ourselves and take critical distance from the objects we work with. That's what Ungers - with Kollhoff, Koolhaas, Ovaska, and Riemann - did in 1977 when writing the incomplete manifesto, "The City Within the City: Berlin as Green Archipelago" (Ungers, 2013[1977]). Focusing on post-war Berlin, they reflect on its shrinking population and rethink abandoned neighborhoods as possible protagonists of a large green area. Each neighborhood is considered a separate city, reduced in scale but highly complex. Possibly a counterpoint to the Plan Voisin, the Green Archipelago deliberately works on the fragmentation of the city, is interested in anonymous architecture, considers the instability of the program as a value, and, in so doing, proposes a novel urban form.

As this case shows, we are trained not only to have an abstract view of the space and its characteristics but also to overlap it with the concrete materials and laws constituting such space. And this capacity helps us see the blind spots. For instance, the previously mentioned perspectives usually take the legal status of the places for granted. That is, although they may refer to private and public spaces, they say nothing about who owns them. This omission seems critical, as it would help better clarify the concrete effects of the distinction between public and private. In fact, land ownership establishes clear boundaries between both forms of space. In terms of property, there are no grey areas.

Furthermore, since Public-owned usually equals State-owned, the urban question becomes political again because the possible uses of

those spaces claimed as public are defined through deliberation between different (political) options. In fact, if the vitality of the city is given by the movement of living people through a politically defined space, public life could also be seen as a biopolitical phenomenon. But even without deepening into those aspects, the very fact that the public/private distinction can be reworked through the lens of land property opens a series of new questions. What would the concept of 'the public' look like if we analyzed it from the issue of land ownership? How many of these spaces described as public require the primary condition of being State-owned? If we want to expand the notion of the public, does that mean we need to increase State-owned spaces? And who would own the public if the State didn't exist?

3. RESHUFFLING THE CONVERSATION

The question of land property also provides a new lens to see modern urbanism. It is well known that the urban proposals of the first modernity were usually deemed so utopian that many of them never found fertile ground. They were also criticized for breaking the city fabric and sometimes even considered antiurban. In some cases—most notably in that of Le Corbusier—the city projects by these first modern architects were treated as the unpleasant reverse of well-received architectural designs. These critiques, however, overlook that the replacement of the old urban fabric implied a total reorganization of land property schemes. What would we think of these critiques if we consider this aspect?

In recent years, a renewed concern regarding the question of property has arisen, leaving a wide body of literature on the subject from several fields[1]. However, in architecture, not so much has been published in this regard. "Reshuffling Urban Land" is an effort to start bridging that gap by opening the conversation of land property within architecture. Considering we have privileged tools to analyze this question, we want to use the lens of property to look at the urban morphologies of modern urbanism. In the end, the traditional city fabric is nothing else than a stubborn crystallization in time of land property regimes. Since land ownership is an endless source of surplus value and, hence, one of the main reasons for economic inequality, the persistence of these regimes implies the exacerbation of inequalities. Therefore, the tabula rasa of modern urbanism seems a genuine possibility to rearrange and equalize the urban.

By recovering these examples, we want to see how the ideas of modern architecture went into the core of economic inequalities by reshuffling land property regimes to generate a different city. Unlike a century ago, we can't be naïve regarding the effects of urban models. Now, about a hundred years later, we know the impact of modern urban proposals, but also that the lack of that impact may not be so desirable. While we may still have the corridor street that Sennett craved, housing is becoming unaffordable, and economic inequalities are constantly increasing. In this scenario, we have the duty to ask: How would we assess the Plan Voisin if we analyze its proposed property regimes? Or who would own the Green Archipelago? ■

1. After the seminal *A Theory of Property* by Stephen Munzer (1990), the topic has been retaken in the last ten years. In 2013 Andro Linklater published the huge *Owning the Earth, The Transforming History of Land Ownership*, reopening this field of inquiry. In 2018, Brenna Bhandar linked the question of property to the colonial project in her brilliant book *Colonial Lives of Property*. Robert Lamb wrote in 2021 a thorough review of this concept and, only recently in 2023, architecture critic Rowan Moore published a critique of how this idea built the contemporary world.

THE DRIVERS AND OUTCOMES OF THE URBAN RENEWAL IN OKLAHOMA CITY: LOOKING BACK, LOOKING FORWARD

SELENA BAGNARA MILAN
UNIVERSITY OF NOVA GORICA; USACE-EUROPE

ABSTRACT

During the Post-War era, Oklahoma City was the stage of the implementation of the I. M. Pei Plan, a top-down urban development initiative having both production and consumption orientations. It was a by-product of the necessity to converge institutional functions, trade services, as well as entertainment and leisure activities, in a very dense area.

Criticized and never completed due to drastic cuts in federal funding, a depressed economy, and lack of public support, the 1965 Pei Plan encompassed the alteration and demolition of numerous significant historic properties, and perpetuated a series of racial inequities and injustices, causing misplacement of minorities; hence, the gentrification of entire neighbourhoods. Although in ambivalent and exclusionary ways, the plan embodied values, which interpreted the needs and visions of local communities through the lenses of the Modern Movement.

As the history of the urban renewal is closely related to the history of the United States of America's Administrative Law, the public-managed bureaucracy and the redevelopment agencies; this contribution aims at outlining the drivers and outcomes of the Pei Plan for Oklahoma City by investigating how this planning tool and its stakeholders dealt with the regime of property rights, the eminent domain practices, and the type of conflicts arising over regulatory takings; and, in doing so, re-shaped the urban landscape and the identities of entire communities.

In conclusion, the phenomenon of the urban renewal in Oklahoma City can be analysed under differing points of view, encompassing its possible sustainable future within the spheres of justice, equity, diversity, and inclusion. Furthermore, it can be evaluated not simply in terms of real estate interests and mobility of communities; but also in terms of envision and creation of spaces during the transition from an era of utopian design thinking to the first postmodern experiments.

1. INTRODUCTION

During the Post-War era (1946-1989), Oklahoma City was the epicentre of an extensive modernization effort, characterized by new interdisciplinary design thinking, as well as by the development and materialization of unconventional solutions.

The urban issues were considered particularly pressing due to the post-war surging in housing demand, the relocation of new economic and leisure activities in urban areas, the unresolved regime of property rights, and the imperative necessity to clear blighted areas.

The above-listed scenarios were accompanied by the expansive reinterpretation of the concepts of public use and takings to encompass the controversial use of eminent domain procedures, which singled out and forced minorities to bear public burdens. These circumstances were the final outcomes of the Great Depression, which saw institutional investors and city governments becoming the major players in the real estate market.[1]

The overall crisis secured the opportunity to foster a movement for the urban renewal of Oklahoma and its capital city. With the concept of "clearing" being the paradigm of the time against preservation initiatives to promote a "city of the future", the strategy embraced in 1965 with the adoption of the Pei Plan required the demolition of hundreds of historic buildings to accommodate large-scale projects. Originally privately sponsored to foster a modern approach to retail for the downtown core, which was expected to become the driving force of the urban renewal efforts; the Pei Plan failed to maintain the promises of the early days of the statehood in ensuring opportunities and allowances for minorities; hence, it led to socio-economic disjunction.

Nevertheless, it is the author's opinion that this model of urban development ensured the manifestation of pioneering solutions in architecture, fostering new forms of organization of life as a "response to the demands of modernization."[2]

2. THE DRIVERS OF THE URBAN RENEWAL IN OKLAHOMA CITY

2.1. THE HOUSING CRISIS AND THE REGIME OF PROPERTY RIGHTS

Following the housing crisis of the Great Depression in the 1930s, property owners welcomed new government regulations, as well as the creation of the Homeowner's Loan Corporation (HOLC), the Federal Housing Administration (FHA), and special federal programs,[3] which increased the chances for government intervention in the overall real estate market. At the same time, urban renewal advocates — *in primis*, business leaders —, promoted the reinvigoration of public-private partnerships through programmatic rhetoric, the media, and futuristic exhibitions. Furthermore, they advocated for the adoption by city planners of specific "master plans" generated by internationally acclaimed consultants of their choice.

2.2. THE PRACTICE OF REDLINING IN OKLAHOMA CITY

Created in 1933 by the Roosevelt Administration to rescue working- and middle-class families from the housing crisis of the Great Depression, the

2. Kenneth Frampton, *The Other Modern Movement: Architecture, 1920-1970* (Yale, CT: Yale University Press, 2021), XXI.

3. Federal programs, such as the National Housing Acts of 1949 and 1954, helped financing the construction of military housing and dwellings for returning soldiers. They influenced the planning of many cities by introducing the concept of "urban redevelopment."

HOLC had the mission of supporting existing homeowners undergoing foreclosure by issuing amortized mortgages.[4] To avoid excess risk, the HOLC created maps of every metropolitan area in the nation: they were colour-coded with reference to the level of risk, which was represented by the type of community residing in the neighbourhood, specifically by its ethnicity and national origin. Oklahoma City was surveyed and mapped following the aforementioned method (**Fig. 1**). As such, a hazardous district was demarcated with a red colour (redlined neighbourhood)[5] if African Americans or other minorities lived in it; hence, yielding to discriminatory regulations and planning.

The forced "urban removal" had far-reaching and long-term consequences on communities of colour, causing disruption of both social cohesion and sense of place.[6] It interrupted the natural transition process, causing severe distress and generational trauma, which compounded with the sufferings caused to Native Americans by the historic "Trail of Tears."[7] Taking into consideration that for Native Americans human and civil rights are intrinsically dependent upon the availability of land; their stance to achieve self-determination and tribal sovereignty were affected by both the deprivation of reasonable resource allocation and the subsequent relocation in degraded areas.[8]

3. PLANNING A MODERN CITY

As Oklahoma City had experienced the phenomenon of the urban sprawl between the 1940s and the 1950s, the exhaustion of parking availability downtown, and the consolidation of new traffic patterns and needs; the original small lots and public areas were deemed inappropriate for modern business and leisure activities, pushing the local retailers outside the capital city.[9] Additionally, there was a great demand for public projects, such as convention centres, theatres, and gardens.

The city leaders were determined to carry out a program that would transform Oklahoma into one of the most pulsating urban centres of the nation. In the midst of the Civil Rights Movement, these urban initiatives did not comprehensively address the sustainability of the envisioned futures in terms of human, social, environmental, and economic prosperity.

3.1. THE OKLAHOMA CITY URBAN RENEWAL AUTHORITY

To establish an efficient spatial governance system, business leaders, media owners, and philanthropists ensured local and state laws authorized and facilitated land acquisitions for redevelopment to the extent that eminent domain practices, for example, were widely accomplished by offering minimum compensations.

In this context, the City Council authorized the creation of the Oklahoma City Urban Renewal Authority (OCURA) in 1961. It was established as an independent board consisting of five members that would secure federal funding to acquire and develop the areas of blight designated by the City Council, and empowered through state laws with financial resources and legal apparatuses.

Simultaneously, a group of business leaders organized as Urban Action Foundation (UAF)[10] hired a project delivery team led by international architect Ieoh Ming Pei, and provided significant monetary support to OCURA during the 1960s.

At the time, Mr. Pei, a 1946 Harvard graduate, was a promising professional, who had already "advised several urban-renewal plans for areas of Washington D.C., Boston, and Philadelphia."[11] The architect was designated to bring the city to its centennial celebration of 1989 by developing a General Neighbourhood Renewal Plan for the downtown business district with a focus on the shopping centre "Galleria" and apartment's space. It was the so called No. 1-A Project covering a 140-acre area, which would become the public face of the urban renewal in Oklahoma City, representing the entirety of the city's redevelopment for over two decades.[12]

In the 1960s, there were other two key projects undertaken by OCURA and located in the 1-B area: the University Medical Center Project and the John F. Kennedy Housing Project. Both were located on the Eastside District, the African American section of the city (**Fig. 2**).

3.2. THE CONCEPTS OF BLIGHT AND SLUM CLEARANCE

To build the new Oklahoma City's skyline and complete the desired civic and leisure projects, such as the Convention Center, the Myriad Botanical Gardens, or the Mummers Theatre;[13] the Pei Plan commenced the demolition of a multitude of downtown structures — mostly, African American neighbourhoods —, and the destruction of significant historic properties, stirring public resentment and remonstration. Although the local chapter of the Congress of Racial Equality asked for a repeal of the urban renewal plans,[14] the City Council was reluctant to direct other agencies to find alternative areas for minorities. The concerns of the African American residents were focused on the concept of "blight" and "slum clearance" under the guise of which their communities had been relocated.[15] According to the local newspapers of the time, African Americans denounced the violation of their personal rights and the unfair transactions of homes purchased on the Oklahoma City's Eastside by OCURA.[16]

It is to note that at the beginning of the 1960s, the segregationist policies and practices influenced by Jim Crow laws were still radicated, including segregation in schools; and the African American Civil Rights Movement in Oklahoma was still on the path to the advancing of anti-discrimination legislation.[17]

3.3. THE HOUSING INEQUITABLE POLICIES

The FHA, created by Congress and President Roosevelt in 1934, fostered and reinforced the previous malpractices by institutionalising racial discrimination in the housing market, extensively using biased information developed by the FHA itself and the HOLC.

The school desegregation fostered by the *Brown v. Board of Education* ruling[18] became of particular concern of the FHA, which established inequitable policies in its 1952 *Underwriting Manual*[19] meant to discourage banks from issuing government-backed mortgages or financing entire

subdivisions to minorities. It coined concepts such as "inharmonious racial or nationality groups," and called for "compatibility among the neighbourhood occupants" to obstacolate integration. It also encouraged the use of restrictive covenants to enforce "homogeneity."

4. THE PEI PLAN

The Pei Plan was based on several interlocking systems, which included the wish-list items promoted by the city government for years: an arts district centred on a theatre (Mummers Theatre), a park (Myriad Gardens), and a convention centre (Myriad Convention & Civic Center). These "items" were complemented by a retail shopping core, a business and an office district, a major residential area; as well as by spaces for hotel development with new parking garages.[20]

Due to the lack of funding and public support, and as a consequence of the economic crisis of 1982,[21] any redevelopment projects associated with the Pei Plan entered into a sunset phase in the 1980s, leaving the program half-finished and revealing a shapeless, fragmentary downtown. Whilst the new workplaces had materialized, the recreation projects were only partially completed, and the new living areas still to emerge. In 1993, Oklahoma City's residents funded the MAPS program to "turn around their struggling city through an approach designed around the feedback received by the communities."[22]

4.1. PLANNING FOR MONUMENTALITY

Notwithstanding its undeniable flaws and shortcomings, the Pei Plan had the distinction of planning for monumentality. By opening up a path to renaissance for the city, it encompassed the transition from the Post-War's multidisciplinary and programmatic approach (*Think Tank*)[23] epitomised by Brutalism-style architecture as cultural expression of the collective crave for progress and stability; to the heterogeneous postmodern experiments of the Poststructuralism era with its epistemological legacies associated with the displacement of the modern attitude towards knowledge.

During a time of fluid experimentations, the most striking example of postmodern architecture in Oklahoma City was the first completed project of the Pei Plan: Mummers Theatre (1969-2014), designed by the Harvard-trained architect, John M. Johansen, who was inspired by the machine and its functionality, and changed the dominant "all concrete" vocabulary through the application of the concept of adhocism (**Fig. 3**).

Originally conceived by the Pei Plan as a 1960s typical two-story auditorium, the new city theatre was the result of the vision of the local performance group and his director, Mack Scism, who had a progressive approach and gained the attention of the Ford Foundation with its nationwide grants system; hence, moving the community theatre to the professional level through the commencement of a revolutionary building, which broke the established canons to embrace variety and communication.[24]

The transformative cultural shift represented and endorsed by the postmodern efforts, which coincided with the rejection of the grand narratives, allowed in this instance the co-creation of spaces shaped by the

needs and desires of forward-looking groups, who combined forces with public and private stakeholders to support and serve the local communities.

5. CONCLUSIONS

The Pei Plan utilized land-use planning concepts on a broad level to establish zoning requirements for specific purposes. It was not conceived and implemented by utilising planning tools that actively involved all stakeholders to ensure extensive participation, transparent decision-making, and the incorporation of a wide variety of interests and needs.

Despite the cutting edge vision for the city that led to the modernization and the inauguration of celebratory landscapes and transformative architecture, the Pei Plan was a product of its time. The plan did not fulfil the needs and desires of all the impacted communities, and did not draw from a comprehensive and unbiased study of the built environment with its sociological and historical aspects. Originally conceived for retail purposes and lately adopted to encompass the vision for the whole city, the Pei Plan failed to consider and represent Oklahoma City as a complex, intricate ecosystem.[25] Regardless its focus on innovation and entrepreneurship, which allowed the materialization of one of the first anti-compositional projects in the country; it worked within traditional frameworks of power. It remained intrinsically unconcerned and unreceptive to the development of progressive initiatives pertaining to race relations and the attempts to open the dialogue to those communities who had been historically excluded from urban planning; thus downplaying the postmodern forces, perpetuating segregation, and missing the opportunity to prepare the city for the future. ■

BUILDING THE MODEL CITY OF SOCIALISM: POST-WWII RECONSTRUCTION OF NEMIGA STREET IN MINSK, BELARUS

DASHA KULETSKAYA
DEPARTMENT BAUPLAN, FACULTY OF ARCHITECTURE, RWTH AACHEN UNIVERSITY, GERMANY

#10

ABSTRACT

This paper traces the post-WWII reconstruction of Nemiga street in Minsk, Belarus. It shows that urban fabric, land property regime, and economic value of urban space are mutually constitutive. The redevelopment of Nemiga was enabled by the communalisation of urban land after the Russian Revolution of 1917. The project, developed in 1972 by a Soviet-Russian architect S. Musinsky and his team, was supposed to become the most ambitious modernist urban development in Minsk. However, for economic and political reasons, its construction spanned more than forty years and was finished only in 2014. During that period, several political shifts caused multiple transformations to the project, eventually resulting in its failure in both urbanistic and architectural terms. To make way for the project, almost all pre-WWII historic substance on Nemiga was razed to the ground during the late 1960s. In this way, all memories of this traditional Jewish district that had existed in the area for several centuries and the underground resistance of the Minsk ghetto were erased. The image of Minsk as a Jewish shtetl on the western periphery of the Russian Empire preserved by Nemiga did not fit the identity of the booming post-WWII industrial capital and the "model city of Socialism." This paper traces the development of Nemiga from the 1920s to the 2010s. While the abolishment of private land ownership enabled ambitious urban development projects in Minsk, it did not leave the city immune to the emergence of new inequalities. The massive privatisation of state housing throughout the 1990s resulted in an unequal redistribution of economic value created during the Soviet period. Moreover, state monopoly on urban land, coupled with the lack of democratic control in today's Belarus, left urban development in the hands of the government-affiliated elites.

1. FROM A JEWISH SHTETL TO THE MODEL CITY OF SOCIALISM

The 1917 Decree on Land, issued shortly after the October Revolution, abolished private land ownership on the territory of the former Russian Empire.[1] Nowhere did the consequences of this decree for urban development turn out to be more profound than in Minsk, a city that over the next few decades would be transformed from a provincial Jewish shtetl[2] to the booming industrial capital and the "model city of Socialism."[3] However, this transformation concerned not only the constructed fabric, but also the population of the city. From 1917 to 1991, the population of Minsk increased more than tenfold, from 154,000 to 1,658,400 people. Simultaneously, the composition of the population according to the nationality reversed. While in 1897, Jews constituted 51.2% of the city's population, in 1989, their proportion reduced to just 2.4%. Over the same period, the proportion of the Belarusian population increased from 9% to 71.8%.[4] While the reduction of the Jewish population in absolute terms was due to emigration and, especially, the Holocaust (between 1939 and 1959, the Jewish population reduced by 48%)[5], rapid post-WWII industrialisation caused the massive influx of Belarussian population from rural areas, leading to the "ruralisation" of the city.[6] Despite its almost thousand-year history, post-WWII Minsk was supposed to become an entirely new city. In this context, the reconstruction of Nemiga posed a clear challenge to the Soviet authorities. The narrow, crooked street, built-up mostly with two-to-three-storey masonry buildings and log huts, had to be made fit for its new role in the centre of a Soviet capital.

2. NEMIGA AFTER WWII: NOT QUITE A *TABULA RASA*

Soviet publications on the post-WWII reconstruction of Minsk mostly refer to the post-war city as a *tabula rasa*.[7] Although at least 80% of the built volume of the city was indeed destroyed during the war, some districts remained intact. The area surrounding Nemiga street, with its built fabric dating back to the 18th century and its morphology back to the 12th century, was one such district. The northern side of Nemiga was historically inhabited by the Jewish population. During the German occupation of Minsk between 1941 to 1944, this area became the Minsk ghetto.[8] It is important to note that the history of the Minsk ghetto was different to that of other Eastern European ghettos, since there were no attempts to initiate a military revolt or uprising as, for instance, in the Warsaw ghetto. Instead, Minsk Jews decided to flee into the woods and join the partisan movement.[9] The absence of military resistance inside the ghetto was also one of the reasons why the territory of Nemiga escaped full destruction during the war.

To understand why the Minsk ghetto was different, it is essential to briefly review Jewish history in the region. The roots of the Minsk Jewish community can be traced back to the early 16th century.[10] Throughout the 15th-16th centuries, the increasing anti-Semitism in Western Europe caused a large-scale Jewish exodus to Eastern Europe. While Russian, Polish, and, especially, Ukrainian Jews already suffered from pogroms in the 17th century and especially in the late 19th century, the Belarusian territory

remained relatively free of anti-Semitism.[11] This comparatively peaceful ethnic coexistence was mainly due to the absence of nationalist movements and economic backwardness of the region resulting in low levels of economic inequality.[12] This determined Jewish-Belarusian solidarity and the underground movement in WWII Minsk, focused on saving lives by bringing Jews out of the ghetto rather than organising a military revolt.[13] However, after the war, the Minsk underground movement was accused of collaborationism. Many of its members were arrested and rehabilitated only in 1962. Although the memory of the Great Patriotic War[14] was ingrained in the built fabric of post-war Minsk in countless war monuments, the Holocaust and the Minsk underground movement were ignored in the official version of this memory.[15] This led to a peculiar paradox, while Nemiga primarily preserved its pre-war fabric, it had no value to the Soviet government. This situation was further exacerbated by the absence of a dedicated monument preservation department that was only established in Minsk in the late 1960s.[16] The combination of these factors led to Nemiga's planned demolition in the early post-WWII reconstruction plans developed in the late 1940s. However, mostly as a result of economic reasons, the demolition of Nemiga was delayed by almost two decades.

3. FAILED UTOPIA: 40 YEARS OF THE REDEVELOPMENT OF NEMIGA

Despite the protests of the Jewish population and the experts concerned with the preservation of historic heritage, the old Nemiga was razed to the ground in the late 1960s. The first closed competition for the redevelopment of Nemiga took place in 1972, and was organised by the planning institute, Minskproject. The winning project (Figures 1-2) by S. Musinsky, L. Kajar, D. Kudryavtsev, with the participation of V. Dukhanina, A. Kozlenko, A. Volk, P. Geller and G. Koloskova was selected for realisation by the Minsk City Executive Committee. Inspired by the brutalist World's End Estate in London and reminiscent of Ludwig Hilberseimer's Highrise City, the 350m-long complex was due to become the largest commercial centre in the country. However, according to Resolution 274 of the Central Committee of the Communist Party of Belarus and the Council of Ministers of the BSSR "On Further Increasing the Level of Architecture and Urban Planning, Improvement of Housing, Civil and Cultural Construction in Minsk" of August 1973, the State Construction Committee of the BSSR and the Union of the Architects of BSSR organised another open competition.[17] This competition was held in 1975; however, no winner was selected. In 1979, the planning Institute Belgiprotorg, directly commissioned by the Ministry of Chemical Industry of the USSR, began designing an alternative proposal for the eastern side of Nemiga. This was set to be just the beginning of a long series of projects developed for the area. The main architect of the 1972 winning proposal, S. Musinsky, would alone develop at least five versions of the project over the next 30 years.[18]

In 1987, 15 years after the construction began, the western side of the project was not yet finished, and the eastern side not even started. In

the 1987 volume of the architectural magazine *Stroitel'stvo i Arhitektura BSSR* (Construction and Architecture of the BSSR), the 4th issue published a series of opinion pieces, all of which severely criticised the project under construction for destroying the historic fabric of the old Nemiga. Public protest had led to yet another architectural competition for the development of the eastern side of the project, held in 1988. Two years later, shortly before the dissolution of the Soviet Union, the western side of the project was finished. However, the economic crisis of the 1990s, put the construction of the eastern side on hold for yet another decade.

In the early 2000s, the construction of the northern section of the eastern side of the project finally started. This project was constructed by Triple Ltd., a private developer owned by a government-affiliated oligarch named Y. Chizh, was finished in 2012. The architects of the project, S. Baglasov and S. Kozlov, adapted some of the concepts developed during the 1988 competition, including the placement of replicas of the historic facades above a scaled-down version of a raised pedestrian platform. In a way, the façade imitated the historic parcellation of Nemiga (Figure 3). The construction of the southern section started in 2008 and was finished in 2014. This project, which was developed by the architectural office of G. Dulevich, was declared by the authors as an "architectural fantasy" of the old Nemiga. However, its spires, columns, and mansards resemble a poor copy of Stalinist architecture and have nothing to do with the historic architecture of the area. All in all, from the first design by Musinsky and his team in 1972 to the completion of the eastern side in 2014, it took over forty years to finish the redevelopment of Nemiga.

The original project by Musinsky and his team should have been the most ambitious modernist project in the history of Minsk. While the debate surrounding the post-WWII reconstruction of Minsk was concerned with the construction of a glorious socialist future, the 1980s debate was increasingly oriented towards the past. The preservation of the historic heritage became the highest priority in Minsk. This shift doomed the realisation of the eastern side of Nemiga. The project became a postmodern assemblage of historic elements, developed to reconcile the modernist idea with the pre-revolutionary past that was destroyed to make place for it. Unable to bring back lost historic structures, this approach prevented the realisation of the project that could have become future heritage of the "model city of socialism." Instead, Nemiga became a mockery of itself, a monument of the failed Soviet utopia that dismantled the past but failed to construct an alternative future.

The debate surrounding the reconstruction of Nemiga illustrates a much wider opposition between the Soviet and national Belarussian identities. This opposition is represented by two actors involved in the debate around Nemiga: on the one hand, Z. Pozniak, one of the fiercest opponents of the project, and on the other, S. Musinsky, its architect. Pozniak, who was then an art historian, and had protested against the demolition of Nemiga in the 1960s.[19] Later, Pozniak would go on to become a political activist

19. Zenon Stanislavovič Pozniak and Leonid Timofeevič Borozna, "Zabotâs' O Budušem [Taking Care of the Future]," *Pravda*, April 4, 1969.

and the leader of the Belarusian ultra-conservative nationalist movement *Belaruski Narodny Front* (Belarusian Popular Front, BPF). During the 1994 presidential elections, he was one of the main opponents of the winner A. Lukashenko. However, Belarusian society, hit hard by the economic reforms of the post-socialist transition, was nostalgic for Soviet times and failed to respond to Pozniak's nationalist ideology.

Musinsky was born close to the northern Russian city Ustyug, trained as an architect in St. Petersburg (then Leningrad), and came to Minsk in 1952. In his writings about architecture, Musinsky referenced almost exclusively Russian and sometimes Western European examples.[20] Musinsky used decorative elements reminiscent of Old-Russian rook boats and traditional Russian woodcarvings.[21] Although none of them were realised, the appropriateness of such elements for the redevelopment of the oldest street in Minsk is questionable. In an article published in 1987, Musinsky summarises his position towards the historical value of Nemiga:

> *[…] even without being [an architectural historian], I can judge with a certain degree of objectivity the real and imagined values. In my opinion, it is clear to every open-minded person that it is simply not serious to elevate old barns, one- and two-story houses […] to the rank of historical monuments. It is difficult even to imagine how these ruins […] can harmonise with the modern complex of the western side. Of course, it is possible to scrape up enough "convincing" arguments in favor of protecting the "old environment" in the archives, but the strongest argument is life, which dictates its strict conditions for the development of the ancient street. Yes, earlier, when the question of existence of the old Nemiga was still on the table, one could understand the defenders of the architectural heritage. At that time, the whole street had a unique atmosphere and really represented a characteristic historical environment. But now this environment is gone, the main part of the building has been demolished […].*[22]

Bad timing was one of the main reasons for Nemiga's failure. Its historic substance was demolished before the national consciousness for pre-revolutionary heritage could develop. The construction delay of several decades made the original modernist design obsolete. And yet, while the historical value of Nemiga was lost and the symbolic value of Musinsky's project was compromised, the economic value of the area increased significantly due to redevelopment and post-war urbanisation. However, in Soviet Minsk, this economic value was locked due to the decommodification of land and housing. This changed with the dissolution of the Soviet Union.

4. URBAN FABRIC, ECONOMIC VALUE, AND SHIFTING PROPERTY REGIMES

Urban fabric, property regime, and economic value of urban space are mutually constitutive. The abolition of private land ownership in 1917

enabled the realisation of large-scale urban development projects with the disregard for the historic urban fabric across the Soviet Union. In Minsk, the realisation of these plans could truly unfold only during the post-WWII decades. After the dissolution of the Soviet Union in 1991, the property regime changed again. However, the privatisation policies were now determined by the socialist urban fabric. While the Belarusian state continued to exercise control over urban land, individual housing units (mostly apartments) were privatised throughout the 1990s and became the source of increasing economic inequality.

After the construction of the western side of Nemiga was completed, the apartments were distributed according to the waiting list for improvement of housing conditions in the administration of the central district of Minsk. This was standard procedure for most state housing projects. However, while many of the apartments in the complex were indeed distributed according to this list, the proportion of the Soviet nomenklatura living in the complex on Nemiga was higher than in standardised residential complexes. By 1992, it had already become possible to privatise the apartments. While the government aimed to ensure the equal distribution of privatised housing by introducing housing coupons, privatisation was the starting point of increasing housing inequality. Since all urban land remained the property of the state, the privatisation prices of the apartments were calculated taking into account only the age and the construction costs of the building, regardless of its location. This approach ignored valuation dynamics in the housing market, where location and the architectural quality of the building played an important role. Today, apartment prices on Nemiga are one of the highest in the city. In this way, privatisation allowed the first generation of Nemiga residents to capture the economic value produced collectively during the post-war decades.

As for the land on Nemiga, it remains predominantly state-owned. However, to enable private real estate development, the land must be leased or sold in state auctions and thus requires parcellation. However, the Soviet city was planned without any consideration for land parcellation, and its fabric resisted a subsequent parcellation. As a result, the present parcellation around Nemiga and in Minsk in general is a haphazard assemblage of plots mingled with grey zones of no-man's land (Figure 4). In some cases, plots simply outline the contours of existing buildings to define corresponding land areas for the purposes of maintenance and taxation. In other cases, plots seem to be created only to enable the densification of the existing areas. However, even in the city centre, the considerable amount of land lacks any parcellation.

The development of Nemiga over the past century illustrates the profound role of land in urban development and economic inequality. However, despite the abolition of private land ownership in 1917 to address economic inequality in Minsk and lay the foundation for the construction of the "model city of socialism," this did not make the city immune from producing future inequality. ■

BIOGRAPHY

Dasha Kuletskaya is an architect and researcher, working on the intersection of architectural history and theory and economy. Her research focuses on questions of land, value, and architecture in the context of global capitalism. She obtained her PhD with distinction at the RWTH Aachen University (Germany) with an analysis of how commodification and financialisation of land and housing have been unfolding in Minsk and Warsaw since 1989. She is currently a teaching and research associate at the Department Bauplan at the Faculty of Architecture, RWTH Aachen University.

CIAM'S YOUNG GENERATION'S IDEAS OF THE STREET AS A TOOL TO QUESTION CONVENTIONAL HIERARCHIES OF POSTWAR SPATIAL STRUCTURING

ELENA GIACCONE
POLITECNICO DI TORINO

ABSTRACT

In the twenty years following the Second World War, in a liminal period shifting from the effort for reconstruction to the compelling problem of housing a mass society, many young participants in the CIAM's architectural discourse advanced projects and reflections claiming the urge to rethink the role of the street as a crucial *locus* to reconnect to ordinary people and their relational needs, overcoming the abstract and alienating approach of routine functionalism.

The paper argues that, in that context, the idea of the street significantly emerged as a physical and social device capable of questioning the spatialization of social and economic inequalities, proposing alternative conceptions of urban space aiming at rebalancing the organization of preexisting property regimes.

The research analyzes in parallel the Smithsons' socially committed urban exploration in the working-class neighborhood of Bethnal Green (1951-52), their idea for a street-in-the-air applied in the Golden Lane competition's project and informed by the 1930s ethnographers' studies on the longhouses in Borneo, as well as George Candilis' and Shadrach Woods' concept of *Stem* and its application in the projects for the Ruhr University of Bochum (Germany) and Fort-Lamy (Chad) in the 1960s. By positioning those emblematic cases in a much broader constellation of contemporary reflections, the paper insists on the street as the ultimate embodiment of authentic public space and a type-form having a critical generative potential for the future city.

In a period characterized by the speculation of the welfare state machinery and the commodification of architecture, those architects' idea(s) of street witnessed the faith in a more equal redistribution of urban resources that assigned a privileged value to collectivity and relations, resisting both a standardizing functionalist approach and a growing capitalistic system endangering the very existence of public, participated urban places.

1. THE STREET AS DEVICE TO HEAL FROM THE TRAUMA OF WAR

For the new generation of architects starting their career in the late 1940s, the twenty years following the Second World War constituted a liminal period characterized by the hope in the possibility of building a better, more equal society as well as a radical criticism towards the alienating effects of both the rigidities of the CIAM functionalist approach and the increasing bureaucratization of the welfare state's machinery.

Among the young architects entering the CIAM discourse in those years, the British Alison and Peter Smithson and the French-based trio composed by George Candilis, Alexis Josic, and Shadrach Woods, together with the Dutch architects Aldo van Eyck and Jacob Bakema, undoubtedly played a crucial role in bringing to the audience a new set of themes that would have profoundly challenged the orthodoxy of the modern movement. Among the ideas they promoted, the reevaluation of the street as a crucial public space of encounter and exchange and as a starting point to reimagine and reorganize the private and public dimensions of a new society certainly had a central role.

Having experienced, during the conflict, the precariousness of everything that was supposed to be self-evident once peace was restored, they claimed attention to the psychological and relational needs of people, participating in that feeling of nostalgia for the neighborhood scale of living and a world of ordinary, authentic connections with both the landscape and among communities of kinships. In their eyes, those were places demonstrating the value of ordinariness per se, as something that had been unfairly often overlooked, and of ordinary urban forms still capable of accommodating spontaneous human inhabiting practices.

In that perspective, the radical reconsideration of the street as a privileged place of discovery and a crucial element of social morphology constituted a profound shift from the previous two decades of the twentieth century. Far from the monofunctional, univocal conception of a well-defined space relegated to circulation, the streets were meant to comprehend all those extensions of the private house merging into the places of society.[1]

Therefore, during the 1950s, many of the CIAM's new generation of architects started to explore how those spaces between the buildings could foster human everyday life, organizing the unfolding of public and private inhabiting activity.

2. SMITHSONS' INVESTIGATION OF BETHNAL GREEN'S ROUGH, LIVELY WORKING-CLASS NEIGHBORHOOD. THE STREET AS A HUMAN THRESHOLD AND THE ARENA OF COLLECTIVE LIFE

During the early 1950s, Alison and Peter Smithson, together with the British photographer Nigel Henderson, started a series of socially committed ethnographical and aesthetic explorations of the working-class streets of Bethnal Green's neighborhood in the East End of London, persuaded of those ordinary, rough places' potential to reveal something crucial about human being's modes of inhabiting the urban space. Nigel Henderson had moved into the neighborhood some years before with his wife and sociologist Judith

1. Alison Smithson, *Urban Structuring Studies* (London: Studio Vista, 1967).

Stephen, who was enlisted on a study project to gather information about the specific habits and behavior of the local community. The research was part of the Mass Observation Movement, an organization operating in Britain from 1937 until the mid-1960s to record everyday life in the nation.

Smithson's gaze and complex interpretation of the street realm had their roots in those ethnographically inspired explorations and were significantly mediated by Henderson's photographic technique. On the one hand, being precisely situated in Bethnal Green's socio-spatial conditions, their research aimed at building a well-contextualized social documentation of a specific urban reality and a type-form, i.e., the traditional pedestrian street associated with the Byelaw Terraced houses.

On the other hand, as places where the most spontaneous patterns of communitarian everyday life can be grasped, the working-class streets of Bethnal Green also acquired a highly symbolic meaning. As places of the unfolding of collective incidental performances or consolidated habits and traditions, those streets achieved the status of *threshold*, laying in-between the private and the public, the individual and the society, and allowing people to discover themselves through their relationship with the *other* **(Fig. 1)**.

If Henderson's artistic practice significantly influenced the Smithsons' approach to the street study, their interpretation of the street realm also had roots more distant in time, linking their reflections to Tom Harrison's fascination for the longhouses in Borneo.

Harrison was a British ornithologist and explorer who, in the early 1930s, had embarked on a series of expeditions to Sarawak (Malaysia) to study the Dayak's local communities. There, he had been impressed by the reality of the longhouses, large architectural structures that organized the life of many families, connecting separated private apartments through a backbone of shared common areas for cooking, ceremonies, and socialization.

Once in Britain again, Harrison turned his attention "from the rainforest into the street" of his people, thus prefiguring the connection made by the Smithsons between the longhouse, the streets of Bethnal Green neighborhood and their idea of street-in-the-air.[2]

Indeed, Harrison was among the founders of the social survey group Mass-Observation and thanks to the Hendersons' connection and involvement in it, his way of approaching the British industrial towns "as a Sarawak at home" and the typical Victorian byelaws street as another type of longhouse veranda reached and profoundly informed Smithsons' 1950s theoretical and design productions.

Similarly to the Dayak longhouse veranda, the streets of Bethnal Green were observed as direct extensions of the house, capable of balancing family and communitarian needs while remaining permeable by outside visitors. Within those spaces, the boundaries between the private and the public blurred and lost their prescriptive functions toward people's behavior, ultimately undermining the idea of private property.[3]

However, to "take to the street" was only the first step of a process that challenged the very epistemology of the discipline. The term "street" was not used to reassert the value of traditional architectural elements but rather to mobilize collective imagery that was well-circumstantial and in-the-changing at the same time.

2. Mark Crinson, "From the Rainforest to the Streets," in *Colonial Modern: aesthetics of the past-rebellions for the future*, ed. Sehrat Karakayali et al. (London: Black Dog, 2010), 107.

3. Crinson, "From the Rainforest to the Streets," 105.

The idea of the "street" has been forgotten.
It is the idea of the street, not the reality of the street that is important - the creation of affective group-spaces fulfilling the vital function of identification and enclosure, making the socially vital life of the street possible.[4]

Experienced in the byelaws street of Bethnal Green, the new street idea found its most vivid architectural counterpart in the Smithsons' non-realized project for the Golden Lane competition in 1952, whose challenge was to create a design for almost one thousand residents.[5] Located in an area of the city destroyed by the bombs, the projects aimed to demonstrate that high density and tight restrictions on budget do not necessarily result in a low standard of living.

To obtain the greatest possible number of apartments while fostering a heterogeneous and rich neighborhood life, the Smithsons started from the idea that the street would have been the spatial device not only organizing the articulation of the private apartments but also constituting the social space of physical, emotional, and symbolical connections among the hosted families. In Golden Lane, the street realm was translated into a network of "streets in the air" organized on three levels, each constituting a "deck" that welcomed different modes and degrees of human interactions.

Each deck was thought of as a self-contained social entity, a place with its own identity that provided inviting places to linger and communicate with the other inhabitants. Since all the apartments had front doors on the decks and many had a visible yard or garden, many private activities of people's everyday lives became part of the street realm outside. That compenetrating of the house and the street allowed the diverse families to express their own identity and participate in shaping a collective one **(Fig. 2)**.

3. CANDILIS, JOSIC, AND WOODS' CONCEPT OF STEM: THE STREET AS THE PUBLIC BACKBONE STRUCTURING THE NEW URBAN FABRIC

The other idea of the street that this paper discusses was developed by the French-based architectural trio of Candilis, Josic, and Woods (CJW). Compared to the Smithsons', the considered reflections emerged at a later time, mainly from the early-1960s. Almost ten years after their return to France from the North African experience as part of the ATBAT-Afrique group (early 1950s), they started to focus on a different kind of international competition compared to the initial attention on housing, mainly engaging into projects for the reconstruction of urban centers, university poles, and territorial plans. Those constituted challenging spheres of the architectural realm to deal with the emergence of mass society and its dynamic plurality of individuals.

Combining the conviction about the need to approach the problem of density as something intrinsically flexible with a peculiar attention to the street realm as a type-form capable of structuring open, adaptable spatial organizations, CJW developed the concept of "stem," firstly presented on *Architectural Desing* in May 1960, and then implemented in many design projects.[6]

4. Alison and Peter Smithson, *Ordinariness and Light Urban Theories 1952-1960 and Their Application in a Building Project 1963-1970* (London: Faber and Faber, 1970), 45.

5. Bruno Krucker, "Complex Ordinariness", in *Architecture is Not Made with the Brain: The Labour of Alison and Peter Smithson*, eds. Alison and Peter Smithson (London: Architectural association, 2005), 87.

6. Shadrach Woods, "Stem," *Architectural Design 5* (May 1960): 181.

The stem was a linear spatial organization defining a direction for cities' gradual expansion. As for the Smithsons, the idea of the street and not the street was crucial in providing a new ordering and interpretative system to both the city and the design process. By keeping the new parts strictly connected to a central backbone, the stem could accommodate changes, allowing future generations to readapt their spaces while simultaneously expanding through comprehensible patterns of growth.

More importantly, the stem constituted the built frame (the material substrate) hosting people's way of moving and shaping relationships, and, simultaneously, the content and product (the spatial practices and expressions) emerging from human inhabiting activity. Instead of applying rules imposing functions a priori, residents themselves, with their everyday living habits, participated in the design process as actual sources of architectural knowledge.

Among the many projects developed at the time, the University of Bochum in Germany and the plan for Fort-Lamy in Chad are observed as emblematic of CJW's new idea of the street as both the formal materialization and the operative urban device to deal and mediate the apparent dichotomies between permanence and change, individual and collective, internal and external, parts and whole.[7]

Both projects reveal the need to preserve and nurture the public space as anything but static, homogeneous, and flat rather adaptable, permeable, and preserving a certain indefiniteness. That ambiguity provokes people's perception and imagination, raising awareness of public space as something not to be taken for granted but rather as the result of an active act of care against the threat of privatization and urban speculation.

The competition for the new university of Bochum, in the Ruhr area of Germany, was opened in 1962 to establish a new university model for a mass society.

The project proposed by the three partners (that was never realized) exemplifies their strategy to deal simultaneously with the preexistence of the context and the new large scale of a mass university complex[8], by making evident the "reconnecting" value of the street on a physical and a perceptive level.

The proposal was based on the idea of the open space of the "street" as a fundamental educational type-form in the city, alternative to the campus model, regarded as a closed university ghetto.

The large public street was the dominant element defining the relation of the new architecture towards its natural surroundings, while students' accommodations and facilities were implanted alongside it into "clusters".

The idea of scattering around the places for collective activities allowed the growth and change of the whole structure based on the evolving needs of the students' community, ultimately preserving them as active public spaces.[9] Moreover, it constituted an invitation to walk around in smaller or larger groups and encounter other human and non-human presences while wandering in the city-university, thus activating the stem system as the veritable *locus* of learning.

During the early 1960s, the stem was also used as a linear core of public activities structuring an urban extension of Fort-Lamy, the capital of the new Republic of Chad. At the time, Fort-Lamy's administration and urban

morphology were divided into an African and a European quarter, separated by a vast empty area. The latter was the object of the 1961 competition, which demanded the design of four districts to organize and reconnect the city's two parts. Differently from the case of Bochum University, in Fort-Lamy, the stem structured the space on more than one level, penetrating the buildings at varying heights and prolonging the public domain of the street as "street in the air."

In an article published in 1965 on *Le Carré Bleu*, CJW described the project, explaining their choice to preserve the traditional architectural character of the single cell, while not exaggerating its importance for the whole habitat.[10]

The dwellings were disposed side by side on two levels, the upper floor spanning the street so that it becomes an inner element of the house, a public place protected from the sun and the rain. In turn, the cells' number and disposition defined and constituted the street, affirming the value of all architecture, including private architecture, as a public affair.[11]

Aiming to emphasize the relationship between the private house and the public street as mutual-defining elements, CJW introduced the French term of "mitoyenneté."[12]

> Expressing themselves in French, they stated that
> *Ici la notion de voisinage se résume à la notion de mitoyenneté. C'est la continuité de l'assemblage des maisons qui crée l'espace commun public: la RUE.*[13]

The term "mitoyenneté" refers to "une sorte d'indivision s'appliquant à un mur commun séparant deux propriétés contigüs."[14] From the point of view of law, therefore, that threshold belongs to (at least two) diverse owners, each having equal rights over it.

The idea of mitoyenneté was thus introduced to describe something indivisible both on a conceptual level and in its physical spatialization, communicating the value of the "new" street as a fundamentally indivisible threshold of contact between people living side by side and having its proper thickness. The peculiarity of that concept's use is also witnessed by the fact that, in the English version, the idea lost its connotation of direct human contact and impossibility of single ownership, as the term mitoyenneté is translated into "intermediate space."

In the Fort-Lamy project, the street was conceived, once again, as the material substrate and the physical and symbolic product of an idea (i.e. mityenneté), functioning as a structuring element of the new urban fabric and as a public place for citizenship. Indeed, the pedestrian grid penetrating the built environment and organizing the movement of the inhabitants from the car to the house contained a series of heterogeneous covered spaces representing the veritable public core of the new city **(Fig. 3)**.

4. CONCLUSIONS

The examples discussed so far represent only a partial perspective on a multivoiced panorama of architects who, in the postwar period, addressed

the street realm as a central theme to be discussed in dealing with the modern city, undermining any stereotyped distinction between public and private space and predetermined idea about how their design.

Beyond the questionable success of the realized project of the architects whom that paper deals with, their direct engagement with the materiality of the everyday in the street and their associated *new* ideas for modern streets is observed as significantly reshuffling the modes of conceiving and organizing public, private, and collectively spaces.

The new ideas of "street" presented so far appear significant in reaffirming the street space as a place where collective social entities organize their needs together, negotiating a variety of individual desires and expectations and transforming them into shared collective concerns.

Their authors advocate for a still very actual idea of the street as a place capable of raising awareness about emotional and relational people's needs and claiming spontaneous yet stable forms of care and community. Observing the street space as a space of mitoyenneté makes one aware of the risk of withdrawing from participation in the urban public life, delegating, for negligence or disillusion, its ownership and control to single privates and profit-oriented design approaches.

In this perspective, "taking the street," considering it a quintessential democratic space of ordinary public life was (and still is) a practice of resisting the commodification of public space and asserting the rich diversity and specificity of human associations against an overarching generalization in urban planning.[15] ■

BIOGRAPHY

Elena Giaccone (1995) is an architect and Ph.D. candidate at the Department of Architecture History and Project at Politecnico di Torino. She studied between Italy, Belgium (UCL Brussels), and France (Paris La Villette), graduating from an interdisciplinary program held by Politecnico di Milano and Torino. Currently, her thesis investigates the emerging definitions, shifting imageries, and ambiguous interpretations of the concept of Common Man of the Street, as part of the broader postwar CIAM discourse, within the field of urban design. Deeply interested in the pedagogical aspects of architecture, she is a teaching assistant both in Turin and Milan.

ALTERNATIVE CITIES. THE PEVE PROGRAMME, MASS HOUSING PROPOSALS, AND URBAN FORM TRANSITIONS IN 1970S ARGENTINA

SANTIAGO GOMES
DEPARTMENT OF ARCHITECTURE AND DESIGN, POLITECNICO DI TORINO

#10

ABSTRACT

In Latin America, the "Leyes de Indias" that regulated the political, social, and economic life of the Spanish colonies strongly affected the shape of the territory (of its organisation, development, and structuring), determined its property structure, how the land was exploited and worked, and also, influenced its societies, the forms, and hierarchies by which they organised themselves.

In the city of Buenos Aires, the topographical conformation, the characteristics of the soils, and the economic, social, and cultural dynamics have been articulated, consolidating, over time, patterns of occupation, control, and production of urban space in which the grid constitutes basically the only device of articulation between domestic (private) and collective (public) space, acting, simultaneously, as an integrating mechanism and as a materialisation of inequalities. Indeed, the hegemony, strength and pervasiveness of the urban chessboard have survived the reformist instances and modernist formulations of the 20th century, absorbing, and resisting them, consolidating itself as a reference model, parameter, and instrument of comparison and validation of any urban design practice.

Nevertheless, in the 1970s, a substantial series of projects that attempted to completely rethink and reformulate the urban form was implemented, thanks to the impetus given by the *Plan de Erradicación de Villas de Emergencia* (PEVE), (or Slum Eradication Scheme, as it would be known in English). The initiative possesses characteristics which are absolutely exceptional in terms of the quantity, quality, and variety of design solutions built and the multiplicity of designers involved.

Aware of the complex entanglement of reasons that have excluded these experiences from the theoretical and operational study of urban morphology, the paper proposes an investigation of the concrete material outcomes, redeeming the value of an experience that seems to be able to provide indications for designing the contemporary city within a logic of hybridisation and socio-spatial articulation that overcomes the dualities that characterise (not only) the Latin American reality.

1. THE PEVE INITIATIVE. AN UNEXPECTED EXPERIENCE

The housing policies in which the high-density social housing complexes of the PEVE were framed began to be implemented, in broader terms, starting from the years immediately following the fall of President Perón after the *coup d'état* of 1955. From this point, and throughout the period that ended with the advent of the military government known as *Proceso de Reorganizacion Nacional (or the National Reorganisation Process, as it would be known in English)*, the problem of slums dominates the housing debate in Argentina.[1]

The public housing intervention programmes, which involved direct construction, financing of construction companies or the granting of credits to citizens, were a significant translation of the allegedly efficient government model and the relations between the state, the business sectors and large national and international capital, showing how pressure from the latter influenced state policy programmes for housing production.[2]

Planning became a fundamental tool for the promotion of a process of continuous development, and professionals, the bearers of "modern architectural ideas," were welcomed into public offices and called upon to propose a new image of the country that aligned with the dominant ideology, involved in the construction of a "modern" State.[3]

Plans were developed in urban planning following on from the project drawn up in the 1950s by the EPBA based on Le Corbusier's *Plan para Buenos Aires (*or Buenos Aires Plan, as it would be known in English)*4*. These applied the principles of the Athens Charter and introduced elements that went beyond the urban planning model of the first CIAMs which were based on the formulations of Team X.

These town-planning principles, systematised in large-scale plans that never found true application, took concrete form in one-off situations in the state initiatives for the construction of large, high-density social housing complexes, which sprang up as new urban cores within the disintegrated fabric of the suburbs.

The first significant departure from the CIAM principles occurred in the Lugano I y II complex[5], which was a transposition of the British new towns models. The project, supported by the IDB and produced by the technicians of the Comisión Municipal de la Vivienda (or the Municipal Housing Commission, as it would be known in English), was characterised by the ambitious size of the investments, the number of inhabitants, and the demand for industrial production capacity.[6] The reference to European models, with the application of "the most modern techniques of planning"[7], was hoisted as a progressive flag. This formed part of a plan that was showcased in propaganda as a world-class example of addressing large cities' building and social problems.

Starting from these precedents, the research into articulation and reconfiguration of the urban fabric and the effort to achieve formal variety and identifiability found application on a very large scale in the projects for the *Núcleos Habitacionales Definitivos* (Definitive Housing Units) of the

PEVE Plan. Here, disciplinary demands were articulated with the strong constraints arising from the context of action, influenced by the limited economic budget, low levels of dimensional and construction standards, tight timeframes for design and construction, and the interaction with companies and the at-times unclear organisation of administrative bodies.

These experiments, aimed at creating new and complex urban realities, reached their peak at least in Buenos Aires, with the design of two unrealised projects for the construction of two 'cities' of 60,000 and 100,000 inhabitants, in which the configuration of neighbourhood units or uninterrupted urban plots was taken to the extreme and translated onto a vast scale.

2. NEW URBAN FORMS. THE MASSIVE HOUSING COMPLEXES OF THE PEVE PROGRAMME

The 'Elión' project[8] designed by Teresa Bielus, Jorge Goldemberg and Olga Wainstein-Krasuk (Estudio STAFF) in 1969 for a PEVE programme competition, and, above all, the analysis of the project report is very interesting as they introduce new concepts that, when developed into subsequent projects, would contribute fundamentally to the creation of an urban model that characterised the entire period. In fact, even though this is an unrealised initiative, it constitutes a significant contribution to the construction of the framework.

The project was submitted to one of the first PEVE competitions, which was characterised by the introduction of an innovative concept compared to previous competitions for the same operation. In this case, in fact, the tender left the urban design and the choice of the general layout of the complex to the tenderers, without giving any indications on the layout of the buildings or the organisation of the road system.

In the project report, Estudio STAFF stresses how this condition requires the jury to evaluate "not only the price and design of the housing but also the choice and application of an appropriate urban theory."[9] The designers emphasise the importance of addressing the problem of housing starting from urban and sociological premises. They stress the need to take into account the configuration of relational and circulation plots within the complex and then, in close correlation with these, seek to resolve the design of the housing units since "as it is obvious, without an urban approach, any other posterior elaboration is invalid".

The project report goes on to point out the shortcomings of the system of isolated blocks that, while offering a better economic return for the high-density solution, increase the "economic and social cost", creating discontinuity and resulting in disjointed situations due to the loss of the spaces that foster connection and relationship, in other words, of the "small area that in succession unites everything".

Like many others, the Morón complex[10] designed by Estudio STAFF in 1970 is also organised according to an orthogonal plot oriented diagonally to the boundaries of the plot, along north-south and east-west axes.

The buildings are arranged perpendicular to each other, configuring large courtyards enclosed on three or four sides. These courtyards have green

areas and are connected by pedestrian paths bordered by pairs of blocks that, running parallel to each other, connect orthogonally with those bordering the immediately adjacent area. In addition, the connection between all the elements is reinforced by the vertical circulation system that connects the accesses to the apartments by footbridges suspended over the pedestrian streets.

Community facilities, treated independently, are located at the complex's entrances at either end of the main road.

In La Matanza complex[11], designed by Manteola, Sánchez Gómez, Santos, Solsona, Petchersky, and Viñoly (MSGSSPV), the circulation system is generated by a long diagonal axis that crosses the lot and two shorter axes that cross it perpendicularly. The blocks are positioned at forty-five-degree angles to the circulation routes and are connected by external stairs and elevated walkways. In the centre of the complex, there is a long line of apartments that spans the entire lot, and in the space generated between this and the diagonal circulation routes is a public square and a community centre hosting the shopping centre, school, and kindergarten as envisioned in the competition. All social features are arranged within terraced buildings that slope toward the pedestrian plaza or public green areas.

In the project description, the designers claim their intention is to propose 'an urban system that configures a total architectural landscape'. The urban model of isolated blocks "which has failed, in the experiments carried out, to configure an interesting urbanistic proposal" is replaced by the idea of an urban plot made up of the combination of flats, vertical circulation nodes, pavements and vehicular paths. These would configure an urban scheme characterised as "an organic overall proposal,"[12] in which a concentrated density around circulation routes is contrasted with an open fabric in relation to green spaces.

Consistently, the San Isidro complex, also designed by MSGSSPV (**Fig. 3**), is organised around a 'spine' in which community activities are concentrated by linking meeting spaces and commercial and neighbourhood squares (**Fig. 3**, scheme A). The main artery, overlooked by shops and schools, forms a continuous circuit, a 'ring' linked to the street network by three points of contact: two of which are located on Figueroa Alcorta street and another main one providing access from the road, Morón-San Fernando (**Fig. 3**, scheme B).

Along the 'spine' are the *barrios*, made up of 200 housing units each, distributed in blocks of parallel buildings organised around green spaces closed on all sides except one, which opens out towards the surrounding neighbourhood (**Fig. 3**, scheme C). The *barrios* are divided by a pedestrian path that connects the entrances from the perimeter streets, next to which are the main parking areas and bus stops, and the central 'spine' (**Fig. 3**, scheme D). The commercial area is developed along a path on the ground floor (**Fig. 3**, scheme E), which overlooks the public squares of the complex. These are intersected and interconnected by the main lane, which is integrated using the same paving. This creates a continuous perception of the space, which is thus "transformed into a multifunctional area for meeting and different community activities".

11. MSGSSPV, "Conjunto habitacional 'Joaquin', Memoria descriptiva", *Summa 36, Concurso Summa 70, La Vivienda de Interés Social* (April 1970).

12. MSGSSPV, *Summa 36* (April 1970).

The larger Piedrabuena complex[13] is organised into seven cores, each consisting of two concentric semicircles of high and low buildings; the high buildings, with seven to thirteen floors, are arranged along the outer perimeter of the hemicycle, enclosing the low buildings, with three or four floors; these, in turn, define a partially open octagonal green area, housing common spaces or collective facilities.

The cores are arranged along the main circulation axis, with the tallest buildings facing the street and the green area facing the spaces surrounding the complex; the high blocks house, at ground floor level, commercial activities and open passageways that allow vehicles to access the internal area of each core and to the pedestrian routes, which are included between the concentric half-cycles of the buildings.

In Chacras de Saavedra project[14], the experiences of the MSGSSPV group's previous works, especially the Puerto Madryn[15] and Piedrabuena complexes, were taken up. The project envisaged the subdivision of the complex into seven large units, each consisting of an octagonal ring of housing complexes enclosing within it several buildings intended for community functions. The units were configured as barrios, or neighbourhoods, with an autonomous social life, with the presence of 'schools, squares, bars and meeting places', and a clear distinction between 'inside' and 'outside'. The ribbon of housing formed a boundary, resembling a 'wall' of varying height that, while it sloped with terraces towards the inside, presented a homogenous profile on the opposite side, 'giving an almost medieval city-like image towards the outside.'[16]

Each octagon was connected to the others by a double circulation network, one for pedestrians and one for vehicles, which penetrated the units at various points. The circulation system was inserted inside a building platform that also housed the spaces destined for commerce and other collective service elements.

3. A NEW URBAN MORPHOLOGY. ARTICULATION AND SOCIAL RELATIONSHIPS

As reported, the introduction of an urban design that echoed the demands of Team X simultaneously contrasted with the configuration of isolated blocks used until then in public housing construction and the morphology of the urban fabric based on the colonial-derived grid. This was realised for the first time in a project, on an extraordinary scale, in the construction of Lugano I and II. However, the PEVE projects reworked this demand, emphasising the particular importance assigned to the pedestrian circulation system, which was configured as a continuous and three-dimensional plot projected at height through the connecting walkways between the blocks. Nevertheless, compared to the Lugano complex, in the PEVE projects, the pathways only connect the flats.

In the PEVE competitions, in fact, the location of shops and services, when present, was planned within shopping centres, separate from the residential buildings. The traditional city's social life, characterised by the street as a place of gathering and exchange, has thus been deprived of its essential mixed-use character, which the planners have tried to compensate

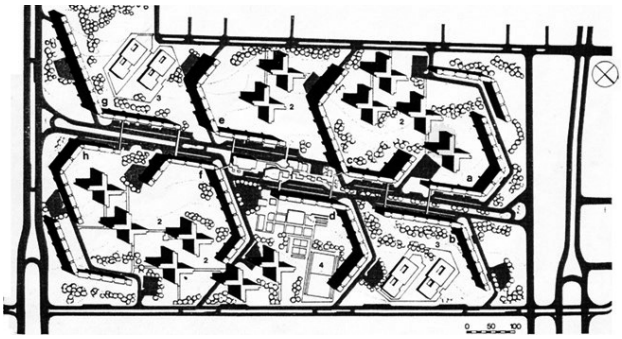
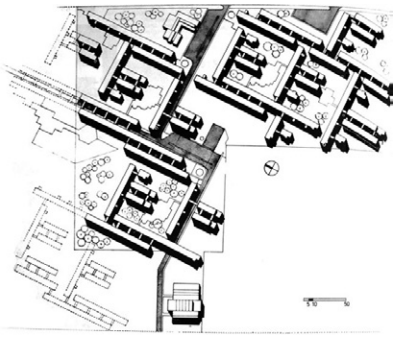
for through a complex formal articulation. The characteristic 'chaos' of the urban street in general, particularly accentuated in Mediterranean and Latin American realities, and determined by the extreme variety of functions, forms, colours and the imposing presence of multicoloured signs of all types and sizes, has been emulated and re-proposed through the use of the only tools in the designers' possession, namely the elements of architecture. Variety was therefore pursued through the introduction of coloured plasters and cantilevering elements, the design of complex circulation systems, the use of macro-graphs indicating house numbers, and the identification of collective facilities. The latter, designed with formal and constructional characteristics is different to residential buildings, reflecting the international mainstream and giving the buildings a strong and clearly recognisable image.



A shared characteristic of all the PEVE complexes, set up as genuine experiments in "alternative cities", was the pursuit of a pattern that articulated spaces and buildings maintaining the pedestrian scale as a continuous reference. The pedestrian plot is a complex system of open-air or semi-covered walkways, sidewalks, common courtyards, and public squares that connect all the residential accesses to each other, to the roads, and to the parking areas. This pathway is defined and delimited by the buildings.



The organisational principle that determined the layout of the buildings was aimed at achieving a progression of spaces, drawing the variety of different places from traditional city elements understood as scenarios for the unfolding of different situations. Recognising different levels of relationships, the projects adhered to configuration criteria at different scales in an attempt to materialise three different areas of relations. Therefore, the pedestrian circulation system had to 'physically' translate individual relationships, recovering the value of the streets, green areas and 'internal' courtyards as places for promoting community relationships (barrio, neighbourhood unit. Additionally, the civic and commercial squares, located in the centre or at the limits of the complexes, were intended to host urban-type gatherings and interactions, attracting the inhabitants - when present - of the surrounding area, due to their functional density.

The pedestrian plot was enhanced by vertical circulation blocks, typically placed outside the buildings, permitting a greater surface area inside the dwellings, allowing for double exposure and contributing to the creation of a 'characterised' outdoor space. In the work of Estudio STAFF, they constituted spaces for gathering and forging relationships, bringing 'richness' and 'variety', while for MSGSSPV, the outdoor location provided a possibility to create a patio-terrace, a nexus between the public and private spheres, for the individual dwellings.

Marina Waisman, presenting the work of Estudio STAFF in 1973[17], underlined how in the projects of the large residential complexes, paradoxically, the attempt to recover contact with the interpretative codes of the users declared by the designers did not pass from the recovery of traditional forms or elements, but rather from the proposal to construct a new urban fabric, which, contrasting with the chessboard conformation typical

of Buenos Aires, was to be configured as the expression of a reformed society, rejecting the settlement principle that was believed to result from the impositions of Spanish domination and that had consolidated as a device for the uncontrolled growth of the city on the basis of speculation.

In this sense, the experiences briefly outlined, regardless of the complex issues they have raised in terms of policies, plans, and the ways in which the state can and must respond to the housing problem, have the merit of having questioned the models of construction of the city's physical space, focusing attention on not only the formal but also the social and symbolic relationships established through living. This indicates more a method (a set of conditions to which the project must respond) or an approach to housing as an urban issue that, with different results and material outcomes, has informed the most recent and interesting proposals for the articulation of fabrics and popular settlements with the urban fabric. ■

BIOGRAPHY

Santiago Gomes is an architect, PhD and associate professor of Architectural and Urban Design at Politecnico di Torino. In 2010, he co-founded Follow the Architect, an award-winning office active in restoration, housing and urban regeneration projects. His professional and research practice has been articulated with social engagement, influencing his interests, positions and work in support of communities and non-profit organisations, contributing through the project to the implementation of inclusive, solidary and sustainable processes. THE LOT IN MODERN ARCHITECTURE URBAN PLANNING: THE CASE OF BRASÍLIA PILOT PLAN'S CENTRAL SECTORS, 1957-

HELENA BENDER
DEPARTMENT OF ARCHITECTURE, UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL

ABSTRACT

History of modern architecture has acknowledged the Brasília Pilot Plan as the epitome of static and unitary planning. Such an interpretation stems from Lucio Costa's 1957 solution, publicised by politicians, architects, and critics as the finished project of a successful political enterprise - a city to be built and inaugurated within President Juscelino Kubitschek's four-year term, summarising Brazil's thriving development. But more than sixty years after the inauguration, the area occupied by sectors for banks, commerce, and services (located around the city bus station) displays tall and disarranged buildings, informal plazas, crowded streets, and construction sites. How can these sectors be so different from the images of Costa's former Pilot Plan? This paper examines such a question by investigating the existence of the lot in the Brasília Pilot Plan's central sectors. Though the lot is a formative structure of colonial cities across America, architects involved in the Brasília Pilot Plan development also utilised it. They experimented with it in different forms and arrangements, organising a complex central area. There, the use of the lot allowed for intense pedestrian transit and commerce, but it also favoured the persistence of empty areas and propriety speculation, raising discussions about preservation and the right to the city. Contrary to the common understanding of urban projects made by modern architecture, the existence of the lot in the middle of the Brasília Pilot Plan partitioned an otherwise indivisible area by bringing the idea of the urban fabric to the very centre of a city usually thought of as a total work of art.

1. INTRODUCTION

In September 1959, the International Association of Art Critics (AICA) celebrated its congress's first sessions in Brasília. The establishment of a congress amidst the early construction sites in the city, combined with a broader effort supported by the Brazilian Embassy to promote Brasília domestically and internationally.[1]

The initiative included the production and dissemination of a magazine (homonymously called *Brasília*), a permanent display at the Ministry of Education and Health in Rio de Janeiro, and the organisation of itinerant exhibitions across Europe, America, Africa, and Asia. In every situation, Lucio Costa's Pilot Plan was presented alongside Oscar Niemeyer's models for palaces and monuments.

Such political propaganda soon created an image which would portray the Brasília Pilot Plan as a significant example of modern architecture's static and unitary planning.[2] What we see today, however, does not align with this idea. Much of the Monumental Axis received additional buildings and monuments,[3] and many different arrangements can be seen across the *superquadras*.[4] This is particularly evident in the central areas, where the vicinity surrounding the city bus station and occupied by banks, commerce, and services, displays tall and disarranged buildings, informal plazas, crowded streets, and construction sites. How could these sectors be so different from the images of Costa's former Pilot Plan? This paper examines such a question by investigating the existence of the lot in the Brasília Pilot Plan's central sectors. Although some recent research has begun to explore the area and its components,[5] there is still a lack of comprehensive studies considering the significance of traditional city structures, like the lot, in its development.[6] Therefore, this text argues that the architects involved in the development of the Brasília Pilot Plan used the lot in different forms and arrangements. Through the lot, they favoured the organisation of a complex central area, much aligned with the idea of urban fabric.

2. BRASÍLIA PILOT PLAN

Despite the use of the lot since colonial times in Brazilian cities, it is not a planning tool that comes to mind when addressing Costa's Brasília Pilot Plan. Even though the architect had cited the lot in the Pilot Plan Report to address a scheme of individual houses,[7] it does not appear and does not seem to fit in the city's main scheme of two axes intersecting at right angles. In the Monumental Axis, for example, the architect strategically distributed buildings in specific sectors, incorporating civic activities to support the capital's functioning. In the Residential Axis, he organised a series of *superquadras*, each of which had 240-metre sides, to accommodate housing built above *pilotis*. In the first, the city would not change or grow. In the second, Costa designed an intellectual system in which the city would grow through each block or building located on the block. In both arrangements, however, despite dividing the land into large areas, the lot seems to have been excluded, reproducing the idea of a city made in an indivisible site commonly addressed to the city of modern architecture.

6. Some of this argument can be seen in my PhD dissertation "Crônica sobre o fracionamento dos setores centrais do Plano Piloto de Brasília, 1957-1974" (2020), but it is being further developed in the research project "Tecido urbano controverso: um atlas para os setores centrais do Plano Piloto de Brasília, 1957-," at the Department of Architecture, Universidade Federal do Rio Grande do Sul.

7. Costa, "Plano Piloto de Brasília," 14.

In the central sectors, however, the Pilot Plan seems to have deviated from these defined logics. Costa explained that these sectors would be part of the Monumental Axis in terms of composition but similar to the Residential Axis concerning change, growth, and the availability of areas for private enterprises.[8] There were plans to build high-rise buildings that would house financial and commercial institutions, creating the bustling atmosphere of city centres. For this concept to succeed, it should include the participation of different actors in the city-making. Therefore, despite being submitted to previously made master plans, Costa suggested these sectors should be divided into smaller portions and autonomous units and sold in parcels on the real estate market.[9]

3. THE LOT IN THE PILOT PLAN'S CENTRAL SECTORS

Costa did not add any drawings or explanations to the Pilot Plan Report about how the central sectors would be parcelled and sold. Such a procedure was only addressed during the development phase of the Pilot Plan.

3.1. THE LOT AS VOLUME (1957-1960)

One of the earliest documents regarding the development of the central sectors includes photos of a model for the South Banking Sector.[10] These images show the sector as a collection of slab-like volumes placed over a platform. Though some critics noted the images suggested a unified design,[11] leaving no room for the inclusion of different actors, these same images were, at that time, used to promote the sale of residential and commercial areas in the Pilot Plan. They appeared on the back covers of *Brasília* magazine alongside headlines encouraging such purchases.[12] As per Costa's instructions, the central areas were divided and sold in the following years. The construction company Novacap reported sales of "lots," in line with a "purchase and sale commitment of urban lots in Brasília."[13] At other times, the sale being made was of "pieces of land."[14]

However, it was unclear what these "lots" or "pieces of land" corresponded to or how the parcelling of the banking sector was taking place. Even so, the issue can be inferred when one analyses a sequence of articles Niemeyer, author of the design, had published in *Módulo* magazine. In the first one, the architect advocated for a "city planning unity", using the banking sector photo to illustrate his point.[15] In the second, the sector images were followed by three projects, which would fulfil the slab-like volumes prescribed in the model.[16] Using the images of the banking sector, Niemeyer hoped that Brasília would have a healthy influence over Brazilian architects by promoting discipline in the use of forms, masses and open spaces.[17] The following sequence of buildings designed by different architects, for different clients, and with different technical solutions reinforced the idea of the master plan and a set of volumes as tools to control the built form. Each volume would then be a fraction or a parcel of the sector, resembling the recommended approach for the Residential Axis.

Novacap's architects also applied the same strategy to the design of the South Commercial Sector in 1960. They adapted Costa's Pilot Plan scheme into 12 slab-like volumes placed next to the Residential Axis, filling the

17. Oscar Niemeyer, "Unidade urbana."

remaining area with larger and lower volumes. In the drawings for the sector, the architects established a numerical sequence to identify each volume (**Fig. 1**). Each of those placed next to the Residential Axis is assigned a number, following the logic used in the South Banking Sector. However, in the rectangular volumes that make up the rest of the sector, the numbering is doubled: one number identifies the volume, and another the smaller portions. Novacap's architects divided these volumes into parts of four, eight, twenty, and forty metres wide. Instead of creating large, unified buildings, the design replicated the logic of city blocks and lots. The scheme suggests different combinations and possibilities regarding property, such as the merging and unmerging of lots,[18] usually practised in traditional cities.

3.2. THE LOT AS REGULATION (1960-1967)

After Brasília was inaugurated, architects of the newly created prefecture organised a set of regulations to guide new constructions in the Pilot Plan. These regulations established a building height range from two to 12 floors for shops and offices and up to 25 floors for banks in the central sectors. They also described what was understood as "lot": a geometry defined by a combination of height and projections on the soil.[19] Niemeyer justified the measure as a form of controlling and preserving the city's formal and visual unity, which included, besides the regulations, a special service within the prefecture for approving designs.[20]

These regulations were expanded and enhanced in 1967. A new code set and ratified the definition of uses in the central sectors, as the occupation of banks and commerce would also allow offices for tourism and public services, clubs, teaching facilities, and supporting amenities such as cafes, restaurants, and newspaper stands.[21] The code also offered a set of 14 drawing plates, displaying sections and, in some cases, schematic plans of lot division, in terms of a guideline.[22] Furthermore, an additional regulation was established for the building limits for each lot with regard to public areas. In the banking sector, for example, the construction and enhancement of these areas (including platforms and marquees) would also be the responsibility of lot owners, being the prefecture only in charge of enclosing the missing parts (**Fig. 2**). The opposite would occur in the South Commercial Sector, where private intervention was not allowed in spaces outside the lot.[23] With the regulations, the division of the sectors through volumes and fractions, as suggested in photos and drawings up to 1960, was effectively documented as law, and the word "lot" became formally used to identify portions to be constructed by private enterprises in the central sectors.

3.3. THE LOT AS A BI-DIMENSIONAL STRUCTURE

However, the idea of the lot as a bi-dimensional structure, virtually established over the land, appeared solely in the extension plans for the South Banking Sector in 1972. These drawings expanded such a sector towards the south, over an area initially considered as a *superquadra* (**Fig. 3**). The *superquadra* scheme was roughly maintained, including dimensions and the characteristic

strip of neighbouring vegetation. However, instead of keeping the area as one piece of land, they divided it in half with the design of an access road and two parking lanes. The resulting rectangles were named "Lot 33" and "Lot 34", continuing the numerical sequence of the banking sector volumes. In these lots, though, the prefecture's architects did not determine volumes as they did in the 1960 scheme. Instead, they wrote occupancy guidelines in the plan itself, such as the need to provide vehicle parking areas and the maximum height of 21 floors or 75 metres from the ground floor level.[24]

It was also specified that these lots be directly allocated to the National Housing Bank and the Caixa Econômica Federal. These institutions should present a project for approval and urbanise the unbuilt area. As written on the plan: "the allocation of the area to Caixa Econômica Federal is subject to the prior presentation of the program of occupation thereof;" and "the National Housing Bank and Caixa Econômica Federal will have the obligation to urbanise and preserve the unbuilt parts of the areas allocated to them."[25] As confirmed by the subsequent project for the Caixa Econômica Federal, the occupation of these areas began to depend more on the particularities of each project, rather than on the form of a prescribed volume.[26]

4. CONCLUSION

The use of a volume as equivalent to the lot was the first answer architects involved in the Pilot Plan development found to the problem of how to

parcel out the central area and offer it to private enterprises. Subsequently, the introduction of building codes established the usage of the word "lot". The codes also regulated the form and arrangement of structures considered fractional, such as the "lots" of the lower and larger volumes of the South Commercial Sector, while sanctioning the division of ideally unified structures, like the public areas of platforms and marquees of the banking sectors.

The control of the built form, previously managed through volumes, then became intertwined with the bi-dimensional organisation of the lot. Guidelines written in plans and codes made it more difficult to anticipate the building form outcomes. As a result, the indivisible area of the Pilot Plan, and the idea of a total work of art commonly addressed to the city of modern architecture, transitioned to more traditional ways of dealing with private property and building typologies. The combination of different approaches to land division has led to a complex central area, with a mixture of pedestrian and vehicular traffic, diversified commerce, and buildings of varying densities.

However, the lot, combined with non-centred propriety rights, also allowed for the existence of empty and underutilised areas. A recent discussion on the renovation of the South Commercial Sector raised concerns about real estate speculation, the right to the city, and the preservation of the Brasília Pilot Plan by introducing a residential use to boost the area's economy.[27] The idea was not followed through with, but it was a reminder that the area resembles an urban fabric commonly found in Brazilian cities, revealing complexities in the Brasília Pilot Plan and the city of modern architecture that usually go unnoticed. ■

BIOGRAPHY

Helena Bender is an Assistant Professor in the Department of Architecture at the Universidade Federal do Rio Grande do Sul (Porto Alegre, Brazil). Bender is also a member of the research group "Estudos da Arquitetura Moderna Latino-Americana," located in the Postgraduate Program in Architecture at the same institution. Her research interest revolves around the history and theory of the city of modern architecture in Latin America.

‘INFORMAL MODERNISMS’: URBAN DESIGN, PLANNING NARRATIVES, AND NEW CITIES

EMMANUEL OFORI-SARPONG

ABSTRACT

The emergence of modernist urban planning and architecture was an inflection point in the history of spatial organisation around the world. One of the most profound manifestations of the zeitgeist of this period was the birth of large-scale urban projects, such as new cities, envisioned as panaceas to urban social ills. These interventions provided opportunities for modernist ideas to be displayed and tested with relatively limited constraints, especially in the Global South. Purported to be built from scratch, cities such as Chandigarh, Brasília, and Tema became symbols of desirable modernist futures, promising urban existences free from grime and crime. However, the production of these grand modern new cities also led to the creation of what were thought of as ‘informal’, ‘squatter’, or ‘slum’ settlements. These were often designed and built by the people who provided the labour for constructing the modernist cities but could not afford to live in them.

Initially overlooked by many historians of modernism, these ‘informal’ settlements have recently been re-examined, and some have asserted that, given the striking commonality (some might even say universality) of their material and spatial strategies, these should be included in the ‘international style’.[1] This essay explores these built instances as *informal modernisms* and suggests an expanded approach to understanding modernism which includes not only previously overlooked and under-theorised projects by indigenous architects and planners, but also the built environments created by the many whose labour created and continues to sustain modernist cities.

1. INTRODUCTION

The emergence of modernist urban planning and architecture marked a transformative juncture in the history of architecture and planning. Coinciding fortuitously with the end of the second world war, the necessity for reconstruction, the persistence of colonial relations, the rise of new independent states open to grand architectural gestures, and heightened aspirations for human welfare and development, this era fostered an environment conducive to novel ideas.[2] It is therefore understandable that European modernism transcended the confines of that continent, where they originated, extending their reach across continents on a massive scale.

One of the most profound expressions of the zeitgeist was the aspiration to reshape the world through ambitious modernist urban planning and architecture, envisioned as remedies for various social ills endemic to pre-existing urban landscapes. Historical cities – many characterised by dense built forms, labyrinthine streets, organic evolution, and steeped in history, vested political interests, and spontaneity – came under vigorous scrutiny from advocates of modernist ideology. These cities and ways of making cities were perceived as obstacles to progress, and there was a great push for contemporaneous urban fabric better suited to the times.[3]

Proponents of modernism lauded the virtues of rationality epitomised by the grid, citing ideas by Descartes, who said of the historical city: 'one is disposed to allege that chance rather than any human will guided by reason must have led to such an arrangement'.[4] Motivated by such thinking Le Corbusier wrote: 'curved lines constitute paralysis, and the winding path is the path of [the] donkey'.[5] These ideas left very little room for working with and within the constraints of organically-evolved ancient cities or those enclaves created by the majority of city dwellers for themselves.

These grand narratives of modernism propelled the modus operandi of its advocates, which included attempts to rectify perceived deficiencies of old cities through urban renewal projects or the conception and construction of entirely new cities.[6] The former often involved the demolition of existing structures to make way for modernist designs, while the latter involved the creation of new towns, on supposedly empty land that adhered to core modernist principles or variations thereof.

Modernism faced significant criticism for its underlying assumptions, built outcomes, and ways of perception and non-perception. Though several proponents of modernist urban planning approaches tended to couch their aspirations in languages of social justice, there were problematic ideas, assumptions, and oversights.[7] They were seemingly concerned about the squalid conditions endured by urban populations and proposed to ameliorate them in often naïve, sometimes simplistic, and other times ridiculously complicated ways.

Certain cities in this era, especially the so-called 'native quarters' spawned by colonial urbanism in regions in Africa and Asia and even lower-classed sections of industrialized metropolises of Europe and America were often described as in dire straits. Numerous observers of the time, including Jacob Riis in his seminal work on New York, Friedrich Engels' examination of cities like Manchester and London, offered compelling accounts of deplorable urban

living conditions. Yet these accounts should not always be treated as factual and devoid of political intention.[8] As Yeboah argues concerning colonised Ghana (then Gold Coast), such depictions and actions aimed at correcting them were often 'informed by administrative needs and racist assumptions'.[9]

What some modernists failed to grasp was the multidimensional nature of urban environments which encapsulated more than the filth and disorder they perceived. As Jacobs pointed out, many of these were precisely the places that should have served as instructive case studies.[10] Rather, perhaps devoid of diligent observation and driven by an untested vision of utopia, these predominantly male professionals and academics opted to raze many such communities to the ground. In their place, they endeavoured to erect textbook examples of ideal cities, which, in many cases, failed to function as intended.[11] Fuelled by authority and wealth, these 'high modernist' projects represented a pursuit of 'legibility' — the quest by state institutions to oversimplify social dynamics as a means of bolstering social control.[12] In practice, they conflated 'geometric order with working order', thereby administering solutions that sometimes exacerbated rather than alleviated the ills they were intended to remedy in the first place.[13]

Yet while modernist ideas encountered significant opposition in the West and were arguably less able to thrive, it was in states of the Global South, some newly independent and others close to independence, that some modernist architects and planners realized their most significant commissions. Of particular interest here were 'new cities', ostensibly built from scratch. These ranged from new capital cities, industrial towns, or large-scale housing projects, and even to new rural settlements. In these contexts, modernist master plans not only facilitated the provision of necessary infrastructure, but also contributed to the construction of new, modern national identities and served to forge new citizenry that would fit into the mould of the new world.[14] Moreover, liberated from the constraints of the West, and backed by charismatic political leaders, designers found themselves with freedom to test their ideas on scales hitherto unseen.

Despite this, the quest for immaculate cities remained elusive and the grand modernist visions also spawned what we conceptualise in this essay as *informal modernisms*. Informal modernisms refer to those built environments which were typically built by marginalized populations excluded from or neglected by modernist master plans. Often generalised as 'informal', 'squatter', or 'slum' settlements, many of them persist and continue to grow till date as part of town- and cityscapes. In many instances the builders and inhabitants were migrants or locals who had contributed to the construction of modernist cities or provided essential services to migrant workers during construction and several years afterwards.

2. MODERNISM IN THE STRANGEST PLACES?

In his introduction to 'Reading the Architecture of the Underprivileged Classes', Elleh opens with: "How far have we come from the historical architectural avant-gardes' projects of the early twentieth century, those pioneers who wanted to use the medium of architecture to reform urban living and societies around the world?".[15] The book's contributors explore the

aftermath of modernist master planning projects in the Global South, discussing the role of modernist visions in fostering the emergence of 'informal' urbanism.

As has been shown, new master planned cities did not only produce the abstract aesthetics of gridded layouts and white box houses. They also produced so-called 'informal', 'squatter', or 'slum' settlements, often designed and built by people who were not considered or provided for in modernist master plans as well as others who could not afford to live in them (Sarin, 1982). In many instances, these were the migrants or locals who had provided the labour for constructing the modernist cities or who had provided various services such as selling food, and other necessities to migrant workers. They represented, and still represent, a forceful claim – the right to the city – by those who, in many cases, are needed if the urban environments created by architects are to work properly. Many dwellers in these master planned settlements would not be able to survive without the support and services provided by the residents of these enclaves.

Many examples of this abound. In Chandigarh, explosive population growth resulted in the creation of several unplanned satellite enclaves, existing alongside the planned settlement. In 1976, D'Souza reported that in the decade spanning 1961-71 the population living in these 'unplanned' settlements grew by 230%.[16] In Brasilia, three-quarters of its population lived in these informal enclaves by 1980, whilst the planned city struggled to reach the halfway mark of its anticipated population.[17] The story was not much different in Tema. In a paper presented at a UN training workshop for settlement managers at the Kwame Nkrumah University of Science and Technology in 1976, Glover-Akpey asserted that, between 1960 and 70, whilst planned Tema increased by 150% the population of Ashaiman, built by the labourers who built the city, increased by 900%.[18] These claims to new cities represented a defiance of the political, economic, and architectural elites who would prefer their meticulously planned cities remain untouched by marginalised communities and their built environments. As articulated by de Certeau, they embody 'the dispersed, tactical and makeshift creativity' of communities navigating structures of power.[19] Rather than acquiescing to the dictates of the powerful, their creations underscore 'the ingenious ways in which the weak make use of the strong… [lending] a political dimension to everyday practices'.[20] In Brasilia one of these communities fought for and won (legal) rights to live in the city, creating an unexpected addition to the Brasilia dreamed up by its more elite co-creators.[21]

Many scholars and practitioners have defined modernism and modernist urbanism so narrowly as to "deliberately exclude [the] types of architecture built by folks in our urban centres despite the fact that they were, and they remain the products of continued industrialization, expansion of capitalism or corruption, as was the case with the emergence of the celebrated types of architecture…".[22] The reason for this exclusion has often been in the socio-economic circumstances and class of their creators – which means that their aesthetics do not meet middle and upper classes aesthetic aspirations, tastes, and preferences. Another underexplored aspect of this phenomena, as our own research has revealed, are the numerous constructions carried out by otherwise wealthy people but without the influence of formal built environment professionals or their regimes of taste and class.[23]

Considering this, it is useful to consider what we term informal modernisms, inasmuch as they are unexpected and unintended additions to master planned cities, not as the "dark side" of modernism, but as modernist in their own right.[24] This modernism is evidenced in the materiality - by the use of predominantly modern and industrialized materials — plywood, zinc-coated aluminium sheets or panels, recycled oil barrels and repurposed parts of other technologies such as refrigerators visible in some of the constructions. These both represent pragmatic responses to the demands of industrial society and represent aesthetic sensibilities of their creators. Indeed, we suggest that it is perhaps within these under-acknowledged communities that the modernist movement's social justice agenda, aimed at providing universal housing solutions for the urban poor using contemporary materials and technologies, finds its true fulfilment.

3. THE PERSISTENCE OF MASTERPLANNING

In the past five decades or so, modernist master planning has been pronounced obsolete on two fronts: the demise of modernist philosophy and the demise of master planning itself. In his famous 1972 assertion, Jencks proclaimed the death of modernism as coinciding with the demolition of housing blocks in Pruitt-Igoe designed by Minoru Yamasaki.[25] However, this contention, steeped in the assumption of a singular form of modernism and its dependence on Western developments—an assertion challenged by postcolonial historians and proponents of Global Modernism—fails to capture the nuanced reality. Modernist ideas in various guises persisted well into the 1980s, 90s and 2000s. Relatedly, since the 1980s, with neoliberalist roll back of the state and of centralised planning (Baeten, 2017), many declared master planning dead (Verebes, 2013).[26] At the height of these critiques, master planning was increasingly seen as ineffective, divisive and a colonial instrument of domination (Banyikwa, 1989; Njoh, 2009).[27]

These claims notwithstanding, master planning with modernist overtones has persisted in several parts of the Global South (Harrison and Croese, 2022). For instance, over 40 countries in the developing world (excluding China) have initiated over 150 new city projects since the late 1990s.[28] Several reasons underlie the trend in urban development, with variations across states, but common themes persist. As highlighted by Moser and Cote-Roy in their recent review, these projects are often driven by one or a combination of the following factors. Firstly, new urban initiatives provide an opportunity to address challenges in older cities, such as overcrowding, without facing the same levels of entrenched interests and conflicts. They offer a platform for experimenting with governance models that could be difficult to implement in more established urban environments. Additionally, they are motivated by economic incentives to attract investment to stimulate the local economy through the creation of essential infrastructure absent in older cities. Finally, such developments cater to the need for new housing opportunities for expanding populations, especially targeting the urban middle class.[29]

Unfortunately, the lessons of history largely have either been ignored or poorly learned. Many projects continue to privilege the needs and

tastes of the affluent, whilst failing to meet the needs of the marginalised, who invariably support the wealthy lifestyles. Unintended and unexpected additions to master planned cities continue to come up, leading to conflicts and removals by authorities. This leads to questions about how urbanism and architecture might be better deployed to uplift those who need its services the most. Or how can old cities be improved, or new cities be constructed, avoiding the pitfalls of the past and placing human dignity at the centre?

4. CONCLUSION

The need to expand our knowledge concerning modernism and to complicate hegemonic narratives of modernism requires, among other things, that scholars broaden frames of reference to include previously overlooked or excluded places. While efforts have been made, notably by Docomomo towards inclusion of modernism outside Europe, the dominant histories of architecture and construction in Africa for example has meant many of these included examples tend to be the work of European architects. We propose this expanded approach which includes not only previously overlooked and under-theorised grand modernist projects by indigenous architects and planners, but also the 'informal' modernist built environments created by those whose labour created and continues to sustain modernist cities. These merit serious consideration for inclusion in modernist historiography for many reasons, but most glaringly by virtue of their striking parallels with the ideals of modernism touted by the more celebrated and acknowledged stakeholders. As we have demonstrated in this essay, such a perspective not only offers fresh insights, but also enables a better understanding of the early modernist agenda of universal access to the city and the realities of realising this agenda.

Moreover, there are myriad lessons to be gleaned from the architecture of described as 'informal' regarding the creation of cities rooted in principles commonly associated with 'sustainability': the use of recycled materials being one such example. This approach necessitates a profound interrogation of what it means to preserve informal modernisms, given their perpetual state of flux. It invites us to re-evaluate notions of originality, authenticity, and permanence in architectural heritage. Finally, such a move also underscores the need for serious dialogue that engages with the dynamic realities of urban planning and architecture outside architect-planned new cities and metropolises located in the Global North, with theory based on and emerging from the Global South. ■

BIOGRAPHIES

Emmanuel Ofori-Sarpong is an architect with over a decade of experience spanning practice and academia. Since 2018, he has been a faculty member at the School of Architecture and Design at Central University in Accra, where his research-led studios have explored new cities, design for emergency response, and non-pedigreed architecture in marginalised communities. He is currently a doctoral researcher at the School of Oriental and African Studies (SOAS), University of London. His research focuses on the politics of urban design and implementation in post-independence new city projects in East and West Africa, focusing on Ghana and Kenya.

Kuukuwa O Manful is a trained architect and researcher who creates, studies, teaches, and documents the history, theories, and politics of architecture in Africa. She is an Assistant Professor of Architecture at the Taubman College of Architecture and Urban Planning, University of Michigan. She curates adansis£m - a Ghanaian architecture documentation collective; co-runs sociarchi - an architecture non-profit; and is president of Docomomo Accra. PALMAS (TO): CONTRADICTIONS AMONG THE WAYS OF LIVING IN A NEW CITY'S BLOCK

MARIANA VERDOLIN DOS SANTOS
UNIVERSITY OF BRASÍLIA

#11

ABSTRACT

Palmas is a new city in Brazil's northern region, planned in 1989 to be the capital of the state of Tocantins. The city was conceived with an implementation project carried out by specialized professionals. Palmas is structured through a macro-road grid that delimits the boundaries of the blocks and divides it into zones of use and expansion. The project, however, did not include a design for the interior of these blocks. In this way, it is possible to find certain disparities in the occupation process of the residential blocks. Most of them were built by private real estate companies that bought the land from the government in the early years of the city's formation. These blocks were occupied by those that were able to buy the plots sold by the companies. Due to strong real estate speculation, several irregular settlements were built in the areas of expansion and environmental preservation since the beginning of Palmas' construction, inhabited by lower-income families who couldn't afford to buy land in the central areas of the city. At the early 1990s, the government donated plots in three residential blocks near to the civic center so that these families could build their homes; the site is now known as Vila União. The aim of this study is to examine the different morphological and social characteristics resulting from each of these occupations. This will be done by analyzing aspects of urban configuration, such as the distribution of uses and the design of the street network, of two residential blocks in Palmas dating from the same year of construction, 605 South and 305 North. It was possible to verify that the 305 North block, which is part of Vila União, has a configuration that is more propitious to the existence of urban life in public spaces.

1. INTRODUCTION

In Brazil, the 20th century was marked by a strong movement of colonization and urbanization of the north-central territory. As Carlos Santos has explained "the new cities, eager for progress and modernization, are legitimately the materialization of the utopia created by modern capitalist culture"[1]. Palmas, in the state of Tocantins, is one of the most recent examples of a planned city in Brazil, founded in 1989. By studying its process of development and occupation, which has taken place at an accelerated pace and with a strong influence from governmental action, it is possible to see what consequences the rationalization of urban planning has had on the social relations that take place in public spaces.

The city of Palmas was divided, in its urban project, into phases of occupation, in which the city was to be expanded from its civic center. The first governments, even at the beginning of the city's construction, sold a large part of the plots in the expansion areas to private companies. Soon, the more central blocks were occupied by the part of the population that could afford to buy property and, due to the lack of more economical housing alternatives, irregular occupations took over part of the environmental preservation areas. At the beginning of the 1990s, by means of governmental actions aimed at eradicating these irregular occupations and maintaining the preservation of the river valleys, land equivalent to three residential blocks close to the city center was donated to low-income families.

Is it possible to see differences in the morphology of the blocks that came about because of government land donations and those that were occupied through the sale of plots? Aiming to find an answer to the question, this paper will compare two residential blocks, one occupied through the donation of plots (305N) and the other through the purchase of land (605S). Before this, a historical review of Palmas' urban development will be carried out, with a more in-depth analysis of its urban planning, to understand the influence of both the city's design project and government actions on its urban configuration.

2. PALMAS' DEVELOPMENT: A BRIEF HISTORY

Palmas is the capital of Tocantins, a Brazilian state dismembered from Goiás that had its autonomy recognized by law in 1988. The governor at the time, Eduardo Siqueira Campos, saw the opportunity to build a new city to be its capital. A team made up by geology professionals identified the most favorable area for the capital's construction, located on the banks of the Tocantins River, a politically strategic site, in the state's geographical center, with a unique landscape.

Once the site had been chosen, a team was hired to draw up the master plan of Palmas[2]. The proposal defined occupation phases for the city and sought to densify the urban areas. However, due to political mismanagement, the formation of Palmas did not go according to plan and reached parameters of territorial expansion that had not been imagined. In response to this, in the early 1990s, populist governments created measures to control urban sprawl.

1. Carlos Santos, *A cidade como jogo de cartas* (São Paulo: Projeto Editores, 1988), 17.

2. In charge of the team were two architects, Luis Teixeira and Walfredo Antunes.

In the first part of this article the urban project will be presented – how the city was conceived and what was envisioned for its conformation. Then, will be provided data that explains how this occupation took place and the measures adopted to reverse the expansion situation.

2.1. THE MASTERPLAN

The city of Palmas was planned on some levels, according to the principles of modern urbanism. The project was conceived based on the definition of a macro grid of roads that would outline the neighborhoods and guarantee the connection between them, providing continuity in the corridors of streets and public spaces.

The idea was to build the city in ribbons of blocks to avoid urban voids and to set a total density of 300 inhabitants per hectare. However, the project did not foresee urban planning for the block's interiors; they would have a flexibility of implantation within a quadrilateral base of approximately 50ha.

According to Luís Teixeira "Palmas Master Plan defined five phases for urban development, determining areas that should be occupied as the density reached desired levels"[3] (**Fig. 1**). In addition, the proposal aimed to demarcate environmental preservation areas to create limits for urban expansion. Thus, river valleys that cross the urban area were transformed into linear parks.

The aim was for the city to grow along particular directions, starting from the center and spreading towards the determined urban limits, to reduce the costs of setting up urban infrastructure. However, as we will see in the following section, the distribution of the city in oversized blocks, associated with real estate speculation, resulted in a scattered, low-dense city filled with urban voids.

2.2. THE CITY'S OCCUPATION

In his book, João Bazzoli says that "the greed of governments to benefit financially from the sale of allotments to private capital companies has contributed significantly to Palmas becoming a major urban planning blunder"[4]. In addition, according to Elizeu Lira "Palmas represents the greatest example of urban disorganization and chaos, sponsored by a savage capitalism that never measures the consequences of its savagery"[5].

Between 1990 and 1993, less than five years after Palmas' foundation, there were already occupations taking place in the southern expansion zone, scheduled in the master plan to be allotted only in the fifth expansion phase (**Fig. 2**). The result was the concentration of a large part of the low-income population living in neighborhoods very far from the city's administrative center. This results in the disorderly occupation of Palmas, based on the economic interests of public and private initiative, and is responsible for the socio-spatial segregation of the urban expansion.

During this same period, the state government[6] created new settlements close to the urban center in which plots were to be donated to low-income families, as a solution to the growing *favelazation* and peripheralization that was taking place. Corresponding to the area of three residential blocks

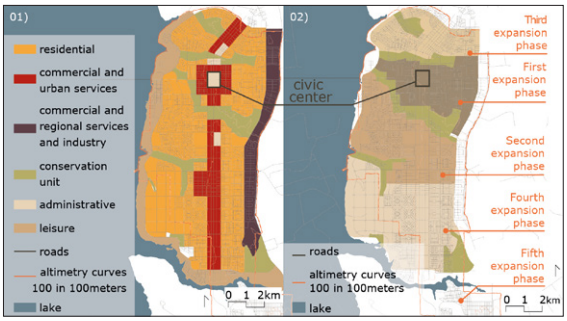
(303, 305 and 307 North), the land today, already fully occupied, is one of the most vital places in the city. It is one of the only locations in Palmas' master plan that can be called as a neighborhood, and is named Vila União[7].

It is possible to see that there is a difference in the urban configuration of the blocks that were built to accommodate the higher-income population and those occupied through an "informal" urbanism as in Vila União. In the next item, this contradiction will be explored by the analysis of two blocks in Palmas: one built according to the city's traditional parameters in residential areas and another that is part of the Vila União complex.

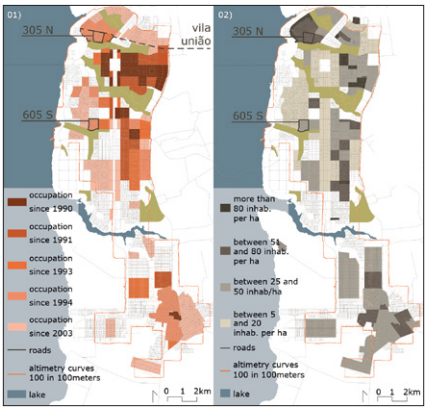
3. LIFE ON THE BLOCK

When you walk through a residential block in Palmas you can see that the streets are surrounded by the houses' fences and the public squares are empty of users and equipment. The impression one gets is that the blocks operate as gated communities, where the inhabitants exclude themselves from social life and avoid the use of public spaces.

In Vila União, on the other hand, the experience is somehow different. There are several neighborhood shops along the way and idle public spaces are almost inexistent compared to a traditional block. As a result, this is one of the only places in the urban center of Palmas where it is possible to experience a neighborhood unity.

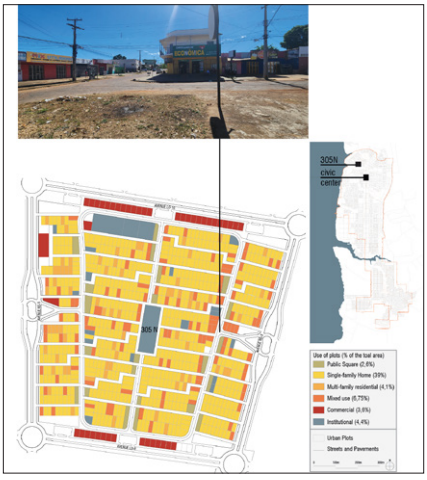


The following sections will analyze the urban configuration of a traditional block in Palmas (605 South) and a block belonging to the Vila União neighborhood (305 North). The selection of these cases was based on their period of occupation, both occupied in 1994, seeking the same time frame for both cases' analysis. By investigating the block' morphological aspects, such as the street network, distribution of uses, density and arrangement of public areas, the aim is to explain the disparity in social relations that occur in these spaces.



3.1. TRADITIONAL BLOCK: 605 SOUTH

The residential blocks in Palmas have an area of around 45 hectares and are on average 600 m long in the east-west direction and 700 m long in the north-south direction. When calculating the public and private areas in the 605 South block, the ratio between them is approximately 1/1. This is because this block, like others in the city, has more than one public square - there are four secondary squares and one main square. These squares, in turn, lack urban facilities, with few, if any, elements that encourage people to stay in these spaces.



The design of the block divides it into two zones, one more internal, with plots approximately 12x30 m in extension, intended for single-family residential use (28.5% of the block's total area). The second zone is composed by plots that surround the boundaries of the quarter, measuring 36x48 m and suitable for multi-family residential use (5.6% of the block's total area). The predominance of plots for single-family residential use is responsible for the block's low population density. The density of the 605S block is around 37 inhabitants per hectare. When comparing 605S's density with other blocks occupied in the same period (**Fig. 1**), except for Vila

7. In literal translation: village of union.

União, it is apparent that this is one of the blocks with the highest density, suggesting that these characteristics have a broader applicability.

Furthermore, when the distribution of uses is analyzed (**Fig. 3**), it is noticed that this block has few commercial and institutional facilities (0.4% and 1% of the block's total area, respectively). There are only some small businesses within the square and two institutional plots, occupied by a church and a leisure club. This means that to reach school and healthcare buildings, residents must look somewhere else.

Frederico Holanda and Rodrigo Vasconcelos describes that "the block has two entrances, east and west, connected to each other by a discontinuous road network, configured by means of a labyrinthine scheme that is difficult to understand, with frequent route inflections and at excessively varied angles"[8]. This makes it difficult for external users (non-residents) to find their way around and contributes to the feeling of not belonging to the place, just like in gated communities. In addition, according to Valéria Silva "when you enter the block, you have the perception of entering a 'different world' in terms of how life is organized in the urban space"[9].

The buildings within the plots that locate along the periphery of the block open out into the neighborhood, while the areas bordering the

roads are mostly empty, exhibiting only the fences enclosing the plots. The transition between the urban scale and the residential scale is not very permeable and public spaces become an extension of private property, as something that belongs only to the residents of that neighborhood.

3.2. A VILA UNIÃO BLOCK: 305 NORTH

Vila União corresponds to the area of the city that encompasses blocks 303, 305 and 307 North, which in turn were planned in the Palmas' original project. The Vila's blocks are very similar in size to a traditional block in Palmas, 47 hectares in extension. However, to Glauco Cocozza "Vila União is a fragment that goes against the guidelines of the urban project, giving it another qualitative condition"[10].

The families who received the plots had to occupy them immediately and stay there. As a result, the first buildings on the block were sub-standard and it was only with the encouragement of subsequent governments that improvements were made to the infrastructure. Glauco Cocozza explains that "little by little, thanks to state incentives and community work, the Vila's image was transformed from a place of invasion to one of the city's richest places in terms of urban life"[11].

In Palmas, municipal legislation allows a flexibility in the occupation and use of urban land: plots for single-family residential use can also be occupied by small businesses and multi-family residential buildings. Thus, in the 305N block, it is possible to find a wide variety of uses within and on the boundaries of the block (**Fig. 4**), which according to Jane Jacobs "is a key factor in producing urban diversity"[12] - local businesses represents 3.6% of the block's total area, while mixed use occupies 6.75%.

What's more, the fact that multi-family residential use is allowed even on small plots like those in block 305N, approximately 11x25 m in size, has led to landowners opting to subdivide the plots and make an extra income by renting out housing units. As a result, the population density of this block is twice that of the 605S block, reaching approximately 65 inhabitants per hectare.

Although the percentage of land allocated to single-family use is higher in the 305N (39% of the block's total area) compared to 605S, the difference in population density is significant. In the process of occupying the block, it was necessary to create a rapid construction strategy so that the families could guarantee their ownership rights over the donated land, which is why the first buildings were small, self-constructed single-family houses. This also explains why there are fewer unoccupied plots in 305N compared to 605S, even though their occupation process began in the same year. While in 305N there was a need to secure land by building rapidly, in 605N the occupation process suffered and still suffers from real estate speculation over plot sales.

The block has a total of 19 accesses to its interior, 17 more than the 605S, which demonstrates its distinctive character in being inviting to external users. Its permeability allows the use of the block to extend outwards. The regular layout of the streets, together with the fewer vacant spaces – instead of big public squares the green places in 305N take place on small plots

allocated on the edges of the internal blocks - and the varied and well-distributed use were factors that gave the Vila a character of neighborhood.

4. CONCLUSIONS

Palmas was one of the last new cities to be built in Brazil. Its recent project (1989) had strong influences from modern urbanism. However, due to flaws both in the city's design and occupation, it did not sprawl as planned. The gaps left by the city's urban design, especially in residential areas, allowed it to develop in a dispersed, sparse, and discontinuous way in urban agglomerations, configured by a linear urbanism of long-distance commuting.

The morphological analysis of the blocks shows that, depending on the configurational aspects and process of occupation, different neighborhood relationships have emerged in the urban space. An area of the same size as that of a block occupied through plot sales, in which relationships are very similar to those of a gated community scheme, may involve other qualities if occupied by social housing programs. An integrated neighborhood, based on community life and the use of public spaces, may emerge and become one of the richest places in urban life in the city. ■

ABSTRACT

Esteemed authors like Arantes, Koury, and Buzzar have highlighted collaboration among architects within Grupo Arquitetura Nova, and its impact on Brazilian modern architecture. Yet, gaps in literature on this group have led to misconceptions, particularly concerning Rodrigo Lefèvre, Sérgio Ferro and Flávio Império. Recent attention has focused on Lefèvre's distinct contributions, notably his 1981 dissertation 'The Work Encampment: A Utopia,' previously unpublished until 2019. This paper aims to elucidate Lefèvre's critical and dialectical approaches, differentiating him from Império and Ferro.

Lefèvre's 'Work Encampment' proposed a transition society in São Paulo, moving from capitalism to socialism. It advocated taxing large construction firms to fund collaborative housing projects with workers and technicians. Lefèvre drew from Urban Anthropology, Eunice R. Durham, Michel Jules Thiéblot, and Claudia Menezes, integrating Paulo Freire's pedagogy to empower workers in defining their urban identity.

His vision rejected oppressive academic approaches, focusing on horizontal education and construction, respecting workers' cultures. Lefèvre's research fostered a new pedagogy and a radical utopia, shifting from rural exclusion to urban inclusivity and political empowerment.

This analysis reveals overlooked aspects of Lefèvre's work, challenging misconceptions and highlighting his innovative contributions to Brazilian modern architecture and social theory.

1. INTRODUCTION

In the 1960s, during the period when Rodrigo Brotero Lefèvre and his colleagues were training as architects, Brazil was deeply immersed in intense debates on its development. In this context, the construction of Brasília became a crucial point of analysis. While some viewed the construction of the new capital as a milestone in Brazilian architecture, others criticised it for not fully leveraging the opportunities for industrialisation and modernisation of production methods.

For Lefèvre, Sérgio Ferro, and Flávio Império, young architects at that time, the critique was not limited to the way the works were carried out but also extended to the political and social aspects involved. They questioned not only the structure of the construction sites but also the working conditions of the laborers and the lack of innovation in civil construction.

Sérgio Ferro, in his text "The Construction Site and the Design," delved into the analysis of the laborers' working conditions and the alienation present in architectural production. In turn, Rodrigo Brotero Lefèvre developed his research in his master's thesis entitled "A Project for a Construction Camp: A Utopia." This work evolved over two decades, reflecting his professional growth as an architect and teacher. He proposed a system that would empower workers to build their own homes, aiming not only to improve living conditions but also to create new social and cultural awareness among construction workers.

These distinct approaches, one focused on economic and production issues and the other on anthropological and pedagogical dimensions, significantly contributed to rethinking not only the architecture of the time but also Brazilian society as a whole.

2. THE WORK ENCAMPMENT

The Work Encampment stands as one of Lefèvre's final formal publications during his lifetime, offering solutions for São Paulo's urban challenges. In this text, we delve into the themes explored in his dissertation, particularly focusing on rural-urban migration and the intricate flowchart devised by the architect for the Work Encampment. Additionally, we highlight the significant influences that shaped his theoretical and critical approach to migration dynamics in São Paulo.

In the "Introduction," Lefèvre tackles the issue of migration into São Paulo, delineating the hurdles faced by migrants as they assimilate into urban life. He underscores issues concerning democracy, culture, housing standards, and employment in the São Paulo Metropolitan Region (referred to as "RMSP"), aiming to grasp, through dialogue with various intellectuals on this subject, the motives and challenges encountered, especially concerning housing, labour unions, and the autonomy of this populace.

In the subsequent chapter, "Why Utopia?" Lefèvre introduces concepts related to utopian ideals, the role of the state, and fundamental rights. He delves into Marxist concepts regarding surplus value, worker exploitation, and presents his envisioned societal model where the State acts as a facilitator of collective will.

Lefèvre rationalises the shift in the State's role within the envisioned societal model. He articulates that, in his model, workers would be provided with the means to fully recover their labour capacity through adequate rest and fair compensation, culminating in their access to a fundamental need: housing.

In this societal model, it becomes the State's responsibility to provide and subsidise the establishment of a temporary encampment, funded through taxes tied to construction activities. This initiative, essentially an investment of surplus value derived from construction workers, aims to address their social and economic integration challenges as a social class. Consequently, the State assumes its redistributive role.

In Chapter II, the architect presents a comprehensive flowchart illustrating the functioning of the Work Encampment during societal transition phases, from migrant arrivals in the RMSP to their integration into social dynamics, fostering exchanges with technicians, engineers, and architects.

It is noteworthy that Lefèvre strategically organises the topics in his work, showcasing the "product" of his reflections early in Chapter II through a flowchart describing the operation of the proposed utopian construction encampment. Subsequent chapters delve into characterising the users and concluding with diagrams of vaulted houses, reflecting his professional journey.

In Chapter III, titled "Processes of substitution, absorption, and preservation of the people's culture by mass culture and erudite culture," Rodrigo Lefèvre revisits the works of author Eunice R. Durham, placing significant emphasis on her influence over other authors mentioned in this chapter. His critique extends to how erudite culture supersedes grassroots culture, suppressing it until it is obscured or obliterated in favour of urban norms.

In the chapter "The Culture of the Work Encampment," Rodrigo Lefèvre analyses studies on rural-to-urban migration and its socio-political-economic dynamics. He draws from numerous authors in Urban Anthropology and Sociology from the 1970s, as well as intellectuals associated with Cebrap (Brazilian Centre for Analysis and Planning) and later Cedec (Centre for Studies of Contemporary Culture) from 1976.

Chapter IV, titled "Some cultural characteristics of migrants," focuses on identifying the emerging working class in São Paulo through Urban Anthropological studies, referencing research by Eunice R. Durham (1978), Michel Jules Thiéblot (1977), and Claudia Menezes (1976) on rural-urban migration.

In chapters V and VI, titled "Some characteristics of the technicians' attitudes" and "Some transformations in pedagogy," Lefèvre revisits his previous works, discussing the evolving roles of higher-level technicians in transitional society. He critiques existing practices while presenting pedagogical methods capable of transforming social relations in the Work Encampment.

Chapter VII, titled "The project of a Work Encampment," unveils Lefèvre's drawings of prefabricated structures, developed based on his prior constructions and utilised as a construction system suitable for the

Work Encampment. These drawings, often regarded as the focal point of the dissertation, have been extensively cited in publications on the architect. Additionally, an annexe to this chapter features comprehensive photographic documentation of the residences constructed by Lefèvre in the seventies, providing a conclusive narrative to the dissertation.

3. URBAN ANTHROPOLOGY

In the late 20th century, as Brazilian urban centres experienced an unprecedented influx of rural migrants, scholars like Eunice Ribeiro Durham and Claudia Menezes sought to understand and document this significant cultural transition. Eunice Durham, in her work "On the Way to the City," explored the process of integrating rural workers into urban-industrial systems, detailing their adaptation from traditional social structures to the complex societal frameworks of city life. Her research highlighted the migrants' shift from a rural existence to urban roles, often constrained by their lack of qualifications for better-paying jobs, which disproportionately placed them at the margins of urban societies.

Durham's analysis revealed not only the physical migration but also a deep cultural shift, examining how these individuals redefined their identities amidst new urban realities. Her work portrayed the migrant's struggle to assimilate into a more segmented and impersonal urban culture, challenging the simplistic dichotomy of "developed" versus "underdeveloped" Brazil.

On the other hand, Claudia Menezes focused on the concept of "change" in her study "The Change: Analysis of the Ideology of a Group of Migrants." She examined the personal transformations migrants underwent during their transition from rural to urban settings. Menezes characterised this migration as driven by a pursuit of improved living conditions, which often occurred without strict planning and relied on informal advice and perceptions of success from others who had moved before them.

Her research pointed out that migrants, upon arriving in the city, faced profound challenges adapting to an environment that is starkly different from the rural settings they had left behind. The urban landscape, while bustling and filled with opportunities, also presented obstacles such as isolation and the daunting pace of city life, which could lead to a sense of failure and disillusionment among the migrants.

Both Durham and Menezes' insights provided critical foundations for Rodrigo Lefèvre in his master's dissertation, where he constructed a model of a migrant neighbourhood. Lefèvre's approach highlighted the political and social dimensions of migrant experiences, aiming to empower them as active participants in an evolving urban society. His work not only recognised the hardships faced by these migrants but also emphasised their agency in shaping a new cultural identity in their adopted urban environments. This research collectively underscores the intricate interplay of migration, cultural adaptation, and urban development in shaping the modern Brazilian social landscape.

By incorporating Claudia Menezes' insights into the religious and ideological formulation of "success" and Marcel Jules Thiéblot's studies

on the folkloric life in Rondônia, we gain a deeper understanding of the cultural and social dynamics influencing Brazilian migrants. Menezes' work highlights the migrants' perception that success is intertwined with personal virtue and divine will, suggesting that upward mobility is often seen as a consequence of individual effort and, to a lesser extent, formal education. This notion shapes the migrants' aspirations and the way they interpret their experiences in urban settings.

Thiéblot's in-depth exploration of Rondônia's folkloric professionals offers a contrasting perspective on work and cultural identity, emphasising a community-driven, traditional approach that resists the alienating effects of industrial society. His focus on "folkloric professionals" who are rooted in community traditions and values showcases a form of cultural preservation and resistance to the homogenising forces of modernisation and consumption.

Rodrigo Lefèvre, drawing from both Durham and Menezes as well as Thiéblot, uses these insights to craft a nuanced portrayal of the migrant experience in his dissertation. He sees potential in the unique cultural attributes of migrants, which can contribute to a richer, more inclusive urban culture. By emphasising the value of folkloric professionalism and community-based knowledge, Lefèvre challenges the technocratic and capitalist frameworks that often marginalise migrants, proposing instead a model of development that leverages the migrants' cultural strengths for better integration and empowerment.

4. THE PEDAGOGY OF THE WORK ENCAMPMENT — THE INFLUENCE OF PAULO FREIRE AND HIS PEDAGOGY IN RODRIGO LEFÈVRE'S DISSERTATION

The architects of the Arquitetura Nova Group (Lefèvre, Ferro, and Império) discussed the concern that workers were being treated as merely tools on construction sites, used and then discarded when no longer needed, making them an object rather than a subject. Eunice R. Durham's contribution allowed Lefèvre to rescue a cultural and subjective dimension of the construction site worker, which became strategic for the next step towards the pedagogy of the construction site. This approach also incorporated the pedagogical contribution of Paulo Freire, along with Durham, Menezes, and Thiéblot, who were the main references cited in the text "Project of a Work Encampment: A Utopia."

In chapters III and IV, Rodrigo Lefèvre mentions Paulo Freire's works "Education as the Practice of Freedom" (1976), "Cultural Action for Freedom and Other Writings" (1976), and "Conscientization" (1979). The concepts of liberation and conscientization underpin his methodology and enable the new "society" that the architect sets out to describe in his dissertation. With the inclusion of more cited works, the pedagogue becomes one of his main references.

The "freedom" mentioned by Freire is attained when the individual recognises themselves as part of the society they are in, becoming capable of making conscious decisions free from the influence of an "oppressor." The "oppressed" stops imitating the oppressor, thus avoiding the the cycle

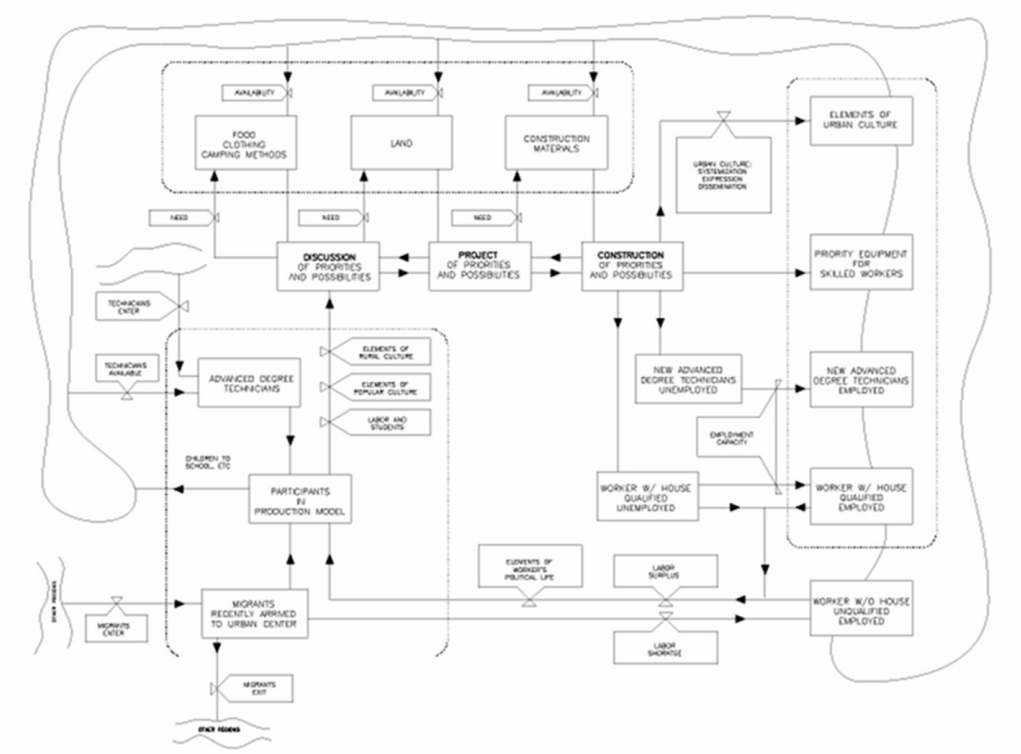

Figure 1. Model of a production during the transition period. © Rodrigo Lefèvre, 1981.

of oppression and building a liberated society. By ceasing to be neutralised by the process of oppression, the "oppressed" has their culture recognised and integrated into a new social dynamic in the Work Encampment. The dialogue between the migrant and the technologist must be horizontal, with an exchange built by two equivalent sides, transforming both the practice of civil construction and the urban reality of São Paulo. Eunice Durham conveys this same idea that the migrant plays an active role in society, as investigated in "On the Way to the City", regarding the political place of the individuals studied.

Due to their physical strength, low formal education, and willingness to accept any opportunity, the worker is often exploited and used as mere tools. Their knowledge and intellect are devalued as they are not seen as "formal" or "academic," resulting in alienated work, limited to receiving and obeying orders without question. Additionally, they are excluded from any involvement in the design processes.

However, these workers learn from what they build and begin to produce their own homes with available resources. These constructions are spontaneous and of no interest to urban technicians, considered useless and consequently disposable by the cultured system of architecture, even though they are the most common forms of housing for these workers establishing themselves on the periphery.

Lefèvre identifies the oppressed within the construction site as equivalent to Durham's migrants. By assigning a role to the migrant's culture in the encampment, Lefèvre proposes, in a practical manner, to

break the cycle of oppression in the construction site and establish work in this environment as an expression of freedom, following the patterns of Paulo Freire's pedagogy. ■

Since 2017, she has been coordinating the Itaim Paulista Laboratory, an extension project involving collaboration with local authorities.

SOCIALIST PRACTICE OF MODERN PLANNING IN THE 1950S'CHINA: THE CASE STUDY OF MINHANG SATELLITE TOWN AND THE ASSOCIATED RURAL PLANNING PROJECT

PENGCHENG ZENG
DEPARTMENT OF ARCHITECTURE AND URBAN STUDIES,
POLYTECHNIC UNIVERSITY OF MILAN, ITALY.

#11

ABSTRACT

As the first satellite town constructed in Shanghai and China in the 1950s, Minhang Satellite Town has been extensively mentioned in research on urban history[1], in sociological studies on urban-rural relations of the Mao era[2], or in mass media reports on the construction of the No.1 Road buildings there, which was once a known socialist boulevard. However, less attention has been paid to the design process and design features of this grid-like satellite town. This study explores the planning of Minhang Satellite Town through analysis of archival and oral history materials. In doing so, it uncovers how its design integrated modern urban planning concepts with local conditions, while also considering the social and political goals of decentralising population and industry from Shanghai city. The planning of Minhang Satellite Town and the surrounding areas was part of the national economic plan and a practical realisation of Mao Zedong's ideals of urban-rural co-modernisation. This study intends to explain the richness and complexity of socialist practices of modern planning ideas in the 1950s, offering insight into the integrity of the 20th-century heritage and the urban-rural relationship in our era.

1. THE IDEA TO DEVELOP SATELLITE TOWNS IN THE GREATER SHANGHAI PLAN (1946-1949)

The concept of developing satellite towns for Shanghai began to take shape between 1946 and 1949. During this time, a group of foreign and western-trained Chinese architects and engineers was assembled to work for the preparation of the *Greater Shanghai Plan,* which was the first masterplan ever designed for Shanghai. Throughout this process, there were three draft versions of the *Greater Shanghai Plan* in total. It has been established that the design of the Greater Shanghai Plan had a close connection to the latest development of planning theories, ideas, and practices of the Western world. For instance, Prof. Li Dehua (1924-2022), who had worked as a technician in the preparation of the *Greater Shanghai Plan*, recalled that some concepts and design ideas applied in the *Greater London Plan* of 1944 such as the regional plan, neighbourhood unit, differentiation in housing typology, decentralisation of people and industry, and so on, had been introduced in the preparation of the *Greater Shanghai Plan* from the beginning[3]. The second draft incorporated the theory of "organic decentralisation" advocated by by Eliel Saarinen, and the principles of "Garden City" promoted by Ebenezer Howard were introduced and applied in the design. The education and professional experience of architects and engineers in the design team also had a significant impact on the design, particularly one of the main architects, Richard Paulick (1903-1979), who had once worked in the architecture studio of Walter Gropius from 1927 and 1930, and it was said that the calculation formula for the minimum building distance for sunlight used in the Greater Shanghai Plan was one of the research achievements from Gropius' studio during Paulick's time there[4].

The Greater Shanghai Plan aimed to decentralise the industries and population from the city centre to satellite towns, so as to improve the living conditions of the urban area. Influenced by Patrick Abercrombie's *Greater London Plan* of 1944, the design team of *Shanghai Greater Plan* also proposed a regional plan for Shanghai and recommended that urban planning be carried out in conjunction with national and regional plans so that the planning and design of satellite towns could be rationally organised from the outset[5]. As a result, the planning area extended beyond the jurisdiction of Shanghai Municipal Government at that time, including Minhang town, which was under the jurisdiction of Shanghai-Hsin (meaning County, in English) in Jiangsu Province at that time, and it was the first time that Minhang town being studied and considered in the planning of Shanghai city.

As per the design principles of satellite towns in the Greater Shanghai Plan, the industrial and residential areas should form a complete urban unit, where the relatively comprehensive urban function should be provided and of which the design standards, such as the population density, the traffic system, and so on, should be the same as in the city centre. This would aid in decentralising both industry and population from the city centre to the outskirts. In the first two drafts, architects and planners had certain

expectations for the improvement of social structure and urban life by means of planning, and they proposed that the Baojia System used in Chinese urban management could be adapted to become a neighbourhood unit system in modern planning. During the preparation of the third draft, they showed a strong desire to reform society, which might have been influenced by the social and political conditions at the time where

the Communist Party of China was winning the civil war by an unstoppable margin. In the report, it was suggested that the development of Shanghai's economy and society was abnormal. The report stated that the *Greater Shanghai Plan* cannot be achieved through improvements in municipal construction alone but requires a thorough reform of the entire society. It was also recommended that Shanghai should be developed into a city focusing on production rather than consumption. The report proposed limiting the growth of the city centre to a certain extent, and intentionally relocating industry and the population to the newly planned districts, such as the satellite towns.

With the establishment of the People's Republic of China (P.R. China) in 1949, the design work of the *Greater Shanghai Plan* was halted and Soviet urban planning specialists began to gain increasingly more influence on the governments. Their negative comments on the Greater Shanghai Plan, along with reduced investment by the Central Government in the construction of coastal cities in the early 1950s, and critiques of modernist architectural and planning ideas, made it impossible to continue with the *Greater Shanghai Plan*. The idea of developing some satellite towns for Shanghai was therefore abandoned. Instead, the continued expansion of urban areas and the use of urban resources to build industrial zones surrounding the urban centre became the main pattern of urban development in Shanghai in the first half of the 1950s.

2. PLANNING OF MINHANG SATELLITE TOWN IN 1958

It was not until 1956 that satellite town proposals gained traction within the authorities with the publication of Chairman Mao's speech *On The Ten Major Relationships*. In this publication, he discussed the issues concerning the development of coastal regions, urban-rural relationships, and so on. In response to the rapid growth of large cities, China shifted its urban development policy to focus on building more small and medium-sized cities. In this context, the Shanghai Municipal Government once again invited once again Soviet experts to Shanghai to discuss the urban development proposals of this city. In the symposium organised for this event, three types of development modes for Shanghai were proposed, including the compact mode, the decentralised mode, and the mode to develop a ribbon city along the Huangpu River. Some architects and engineers who had participated in the preparation of the *Greater Shanghai Plan* years earlier also attended this symposium. Notably, Yaohua Zhong, Huiquan Hu, and Dingzeng Wang seemed particularly concerned about the decentralised mode of developing some satellite towns for Shanghai. While

the Soviet experts did not approve or disapprove any of the proposals in this symposium, an alternative plan involving the planning of satellite towns was studied and discussed among Chinese architects and planners in multiple cities. The idea to build Minhang as the first satellite town for Shanghai has been mentioned on numerous occasions.

The plan to build satellite towns for Shanghai was officially approved by the Municipal Government on January 17th, 1958. This came after the State Council issued a decision to include three counties of Jiangsu Province, Jiading-Hsin, Shanghai-Hsin, and Baoshan-Hsin, in the jurisdiction of Shanghai City. Following this decision, the Shanghai Urban Planning, Survey and Design Institute (SUPSDI) proposed a list of potential sites for satellite towns and the preliminary plans for five of them, including Wujing, Minhang, Nanxiang, Huangdu and Anting[6]. Each satellite town was assigned a major industry and Minhang was planned to be developed into an industrial town manufacturing power generation equipment for the whole nation. Due to its strong industrial and municipal construction base, it was selected as the first satellite town.

The planning was supervised by Zhisheng Qian (1907-1968), the Director of SUPSDI, and the Chief Engineer Huiquan Hu (1913-1968). Both had participated in the preparation and research work of the Greater Shanghai Plan since 1946. Additionally, another key figure in the preparation of the Greater Shanghai Plan was Chief Engineer of SUPSDI, Yaohua Zhong. Perhaps it is for this reason that there are connections between the two plans. For instance, the 1958 plan, similarly to the emphasis in the Greater Shanghai Urban Plan aimed to decentralise both industries and population from the city centre to the satellite towns, rather than building dormitory towns. Furthermore, the living standards set for these satellite towns were even higher than those of the city centre. The ideas, such as classifying roads according to their functions, separating different urban units with different levels of roads, and avoiding arterial roads crossing through residential areas, which were initially proposed in the Greater Shanghai Plan, had also been applied in the 1958 plan.

The 1958 plan for the Minhang Satellite Town differed from axisymmetric layout and large-scale road networks or squares that were common in Soviet planning, instead, planners incorporated a functional zoning and grid layout based on local traffic and geographical conditions. The functional zoning of the 1958 plan demonstrates that the urban area of Minhang Satellite Town is mainly defined by the Huangpu River and three arterial roads. There are industrial L-shaped areas on each side of the Sha Creek, both of which have convenient water and land transportation and are close to the planned power station. The estimated population of Minhang Satellite Town in the 1958 Plan was calculated according to the needs of the factories to be relocated there and the average size of workers' families. The urban grid was determined by the industrial production needs of each factory. Considering that the areas where factories were planned to be relocated in Minhang typically demanded 40 to 60 hectares, the east-west roads in the 1958 planning (the No.I, III, V, and

IX roads) were spaced between 500 to 600 metres apart, and the north-south roads were generally spaced between 800 to 1000 metres[7] (**Fig. 1**). This plan integrated modern urban planning concepts with local conditions, as well as the social and economic development goals of that era, and served as a practical implementation of the national economic plan.

3. AN ACCOMPANYING RURAL PLANNING PROJECT IN THE CONSTRUCTION OF MINHANG SATELLITE TOWN

The planning of Minhang Satellite Town was approved in August 1958, after which the construction projects began rapidly. In order to accommodate peasants whose homes had been demolished to make way for the satellite town construction, several new settlements were constructed outside Minhang Satellite Town. In 1958, the common practice in Shanghai for handling land acquisition and resettlement of peasants in urban development was to directly compensate them and rebuild their houses with the materials obtained from demolishing the old ones in surrounding rural settlements.

7. SUPDRI. "Some Experiences on the Planning of Industrial Development and the Construction of Satellite Towns in Shanghai (Second Draft)." *Shanghai, Shanghai Archives*, January 1960, reference Item no. A54-2-756-.

However, given that the living conditions of the farmers under this policy did not significantly improve, they were not highly motivated to cooperate with urban development. In the construction of Minhang Satellite Town, efforts were made to integrate land acquisition and the demolition of farmers' houses with the resettlement of farmers and the planning of rural settlements. The aim was to reuse the building materials from their existing houses and use a small amount of new materials to build the new settlements. This approach was finally accepted by the peasants, and the issue of land acquisition for factories to be relocated to Minhang Satellite Town was solved within a few weeks. During this period, among the new farmers' settlements constructed was the Yutang Farmers' New Village, which was the largest. It was located east of Maqiao Old Town, west of the No.II Road, adjacent to the Beisong Road, with convenient land and water transportation (**Fig. 2**).

The construction of five three-story peasants' housing units took place in this settlement between November 1958 and June 1959. On July 21st 1959, the Shanghai Municipal Government decided to build this site into a "new type of Garden Village", and listed it, along with the new town centre, as tribute projects for the 10th anniversary of the founding of the P.R. China. Both projects were designed by the First Design Office of the Shanghai Designing Institute of Civic Architecture (DICAS). Yutang Village was built in just 45 days and received positive feedback from society. At the time, it was considered a model that successfully combined urban and rural construction, representing a practical realisation of Mao Zedong's vision for improved urban-rural and industrial-agricultural relations.

The planning of Yutang Village was influenced by both the People's Commune Movement and the planning of workers' settlements in urban areas. The People's Commune emerged from the collectivisation movement of agricultural production, in which the public canteen was designed as a spatial vehicle and symbol of the collective life style. The concept of establishing public canteens in the rural villages originated from the collective canteens spontaneously organised by peasants in the 1940s, and was adopted by some people's communes in 1958. Since then, this concept has become quite popular and functional. Architects now consciously consider this in the planning of rural settlements. For instance, in the planning of Yutang People's new village, the public canteen, which best represented the collective living styles of People's Commune, was placed on the central square of the settlement, with peasants' dwellings surrounding it. Public canteens also became an element of spatial organisation in the planning of the new town centre in Minhang Satellite Town. This shift signifies a move from spontaneous experimentation to formalisation in the planning of urban and rural residential areas (**Fig. 3**).

The design of peasants' housing also went through a similar process. For instance, the three-story peasants' housing units designed by the DICAS in 1958, lacked kitchens for family use and auxiliary areas for storing farming tools and raising poultry, considering that peasants would dine in public canteens. This led to significant dissatisfaction among the peasants,

who spontaneously built their own structures to meet these needs in the surrounding open spaces. Later, the architects revised the housing designs in 1959, adding kitchen spaces to the peasants' dwellings and single-story auxiliary areas on the north side of each dwelling. These spontaneous modifications by the peasants were subsequently recognised and formalised through improved design plans. These cases illustrate how public practices in the 1950s, influenced by the mass line and political movements, were incorporated into spatial elements of urban and rural planning through design.

4. CURRENT SITUATION AND SOME PRELIMINARY REFLECTIONS

In this case, the planning of the satellite town and the farmers' settlement should have been considered as different parts of a complete project. However, as they were under the jurisdiction of different departments after completion, they had never been considered as a whole since the 1960s. As a result, the Yutang Village was demolished without any previous evaluation during the urban expansion in the 1990s. A similar situation also occurred with the new town centre project of Minhang Satellite Town. The project included two residential areas for workers on both sides of the No.I Road and commercial and public buildings along the street. On completion, it received great praise and attention and was recommended to be included in the list of excellent modern and contemporary architecture in Shanghai (1949-2000). However, due to the fact that the buildings on both sides of the No.I Road were under the jurisdiction of different residents' committees, they have been treated differently. During the recent beautification project, the buildings on the south side of the road were transformed into a completely different style, making it seem like the buildings on either of the road do not belong to the same project. Insufficient knowledge and disregard for the characteristics and values of this post-war urban planning and architectural design project have left them extremely vulnerable in the face of complex administrative management and economic development conditions. As a result, the integrity of this type of heritage is therefore highly susceptible to destruction. ■

NARRATIVES-WITHIN A NARRATION: BRIDGING MODERNISM AND CULTURAL IDENTITY IN AFRICAN LITERATURE AND ARCHITECTURE

NTETLENG OREPA MOSIDI
UNIVERSITY OF JOHANNESBURG

#11

ABSTRACT

This paper delves into the intricate interplay between modernism and cultural identity in African literature and architecture, taking Johannesburg, South Africa, as a microcosm. Drawing on Ngũgĩ wa Thiong'o's insights from "Decolonising the Mind,"[1] it explores how narratives within African novels effectively articulate diverse experiences and reassess colonial legacies. The paper extends this notion to the modernist movement in Johannesburg, revealing how colonial mentality and apartheid's spatial segregation continue to shape urban landscapes. Braamfontein's "shop within a shop"[2] phenomenon highlights how African cities adapt modernist structures to create vibrant, culturally rich spaces. Through the lens of Homi Bhabha's "third space"[3] theory, the paper argues for a fusion of modernism and cultural diversity, advocating for a narrative approach in literature and architecture. This approach captures cultural hybridity and reshapes colonial legacies, promoting sustainable urban development and repurposing modernist buildings. The exploration of African literature, mainly through the works of Chinua Achebe and Ngũgĩ wa Thiong'o, underscores the potential of narratives to bridge the gap between African identities and modernity, offering a dynamic blend rather than a mere replication of Western modernism. By integrating multiple cultural narratives into modernist practices, the paper emphasises the importance of contextualising architecture and urbanism within African cultural frameworks, fostering inclusive and representative urban spaces.

1. INTRODUCTION

In the renowned book *"Decolonising the Mind,"*[4] Ngũgĩ wa Thiong'o explores different narratives in the art of novel writing, emphasising their effectiveness in exploring various experiences. He argues that

> *It was imperialism that supplied him with the setting and subject matter of his novels... However, the fluctuating perspectives in time and space, the variety of narrative voices, the narrative within a narration, and the withheld information aid in the reassessment of a prior conclusion, enabling the reader to form a comprehensive conclusion only at the end, once they have gathered all the evidence, information, and viewpoints.*[5]

The above notion goes beyond literature and can be crucial in examining the modernist movement in Johannesburg, South Africa, as well as the broader context of Africa's encounter with modernism. Lindsay Bremner[6] also argues that the portrayal of colonial mentality and the continuation of apartheid's spatial design and segregation not only ignore the hopes of South Africans and other Africans living in Johannesburg but also clearly define racial divisions, pushing non-white South Africans to the peripheries of the city and immigrant Africans to embody narratives within narration in modernist buildings seen in inner cities. This layered interaction between city dwellers and modernist planning has dramatically influenced the spatial dynamics observed in Johannesburg, creating a fascinating contrast with the original principles of the modernist movement and apartheid ideology while simultaneously embodying cultural existences. Specifically, the observations made in Braamfontein, Johannesburg, as discussed in earlier research on the *"shop within a shop"*[7] concept, lead us to contemplate the potential outcomes of exploring identity narratives in architecture and urbanism. Thus, this exploration reveals the need for a fusion of modernism and what Homi Bhabha refers to as the *"third space"*[8]—a means to embody cultural variety, particularly on the African continent, with Johannesburg serving as a microcosm. The paper then delves into the methodology for investigating how modernist African literature uses narrative to reshape the legacies of colonialism and apartheid. It argues that a narrative approach can capture cultural hybridity, allowing for a proper contextualisation of modernist practices in architecture and urbanism. This paper will explore a notable example, the *"shop within a shop."*[9] To discuss this, Stephanie and Lindsay Bremner's works highlight the importance of narrative in Western practices and forms on the African continent. They also establish connections between African literature and narrative, spatially embodying culture and its diversity through the coexistence of Africans of multiple origins in one space. To promote sustainable urban development and the repurposing of modernist buildings or any other architectural style introduced to Africa without considering precolonial practices or spatial traditions, this paper explores South Africa's broader and specific contexts. Language and narrative in African novels often serve as powerful tools for capturing the essence of location, geography, and architecture, thus beautifully encapsulating the rich cultural

tapestry. Exploring the relationship between African cultures and identities and African literature enhances our understanding of their manifestation. In her chapter entitled *"Listening to the City,"*[10] Lindsay Bremner explores the use of narrative to understand and improve the development of African cities. She suggests that introducing modernist architectural practices to the continent overlooks or disregards Africans' deeply ingrained cultural uses of space.

2. MICROCOSM: MODERNISM IN JOHANNESBURG, SOUTH AFRICA, AS THE EMBODIMENT IF COLONIAL LEGACIES

The late 19th century heralded the arrival of modernism, a movement that profoundly influenced South Africa's architectural and urban landscapes[11]. However, in this context, modernism found itself intertwined with the harsh realities of apartheid, revealing the deep-seated racial and cultural segregation entrenched in the country's urban planning. After gaining independence in 1910, South Africa clung to a colonial mindset, a sentiment starkly embodied in the Group Areas Act of 1950[12]. This legislation imposed rigid spatial boundaries, systematically segregating communities by race and perpetuating the colonial legacy of division. Rather than fostering inclusivity or innovation, modernist principles entrenched exclusion and inequality, explicitly targeting non-white South Africans. Jean and Jean's analysis of colonialism accurately describes how colonised nations frequently served as experimental grounds for colonial powers, resulting in urban centres teeming with a rich cultural tapestry. They argue,

> *Today, the inner cities serve as the ground on which the spatial and temporal coordinates of the past converge and where the metropole and empire's margins fold into one another. Former colonial subjects-turned-immigrants reside here, usually on the outskirts of a political economy that increasingly provides them with little formal employment, recognition, or rights.*[13]

The arguments above are palpably evident in Johannesburg, where the 'Shop within a Shop' phenomenon in areas like Braamfontein showcases this blend of diversity and economic adaptation. See **Fig. 1** below.

Braamfontein was initially envisioned as a white suburban area under the Group Areas Act, but it now stands as a testament to resilience and cultural hybridity. The area has transformed into a bustling enclave of African communities from across the continent, creating a vibrant mosaic of cultures and practices. Homi Bhabha's concept of the third space is crucial here. The third space forms hybrid identities outside the binary oppositions of colonial discourse. It is a cultural exchange and transformation site where marginalised voices can articulate their experiences and identities[14]. In earlier research, drawing on the works of Tsitsi Dangarembga[15] and Frantz Fanon[16], the notion of a nervous condition was explored—a psychological state born out of cultural displacement and hybridity. Such a condition is evident in Johannesburg's architectural styles and movements, where the facade materiality and structural design reflect a confluence of African ingenuity and

modernist principles. Africans, particularly in Braamfontein, navigate these modern spaces, subtly challenging the rationality and austerity that characterise modernist architecture. The 98 De Korte Street building exemplifies this intricate dance between modernism and African spatial practices. Designed as a sleek, minimalist structure, it houses diverse retail spaces on its ground floor, where traders from Congo, Nigeria, and other Sub-Saharan African countries engage in commerce. This 'Shop within a Shop' phenomenon disrupts the original intentions of the building, infusing it with a vibrant, multifaceted life that mirrors its occupants' economic realities and aspirations. The demographic landscape of Braamfontein has evolved significantly since the enforcement of the Group Areas Act. Initially intended for white residents, the area now reflects a rich demographic mix.[17] See **Fig. 2** below.

The coexistence of various narrative voices within its spatial complexities is reflected. The influx of African immigrants and internal migrants has transformed Braamfontein into a microcosm of pan-African diversity. This shift challenges the economic marginalisation often imposed on these communities as they carve out spaces for economic activity and cultural expression within the urban fabric. Under the guidance of the late Gerald Chungu, we explored this phenomenon in 2017, observing the repurposing of these modernist structures to cater to the economic needs of marginalised communities. The coexistence of various African traders within a single retail space underscores the adaptability and resilience of these communities as they navigate and subvert the spatial limitations imposed by apartheid-era urban planning. Modernist planning in the context of the Group Areas Act of 1950[18] and cultural hybridity weaves a narrative into the continuance of modernism in South Africa. Johannesburg's Braamfontein serves as a living testament to this complex history, reclaiming and repurposing modernist buildings originally intended for exclusion to promote economic development and cultural integration through adapting African ingenuity and spatial practices. This phenomenon challenges the rigid canons of modernity and enriches our understanding of African modernities in a broader context.

3. ABSTRACTION: FROM AFRICAN LITERATURE TO HYBRID MODERNISM

The historical impact of colonialism in South Africa and across the continent has often distorted the concept of modernity, tying it exclusively to European influences[19]. This marginalised African existence placed it outside the scope of modernity. In "Critical Terms for the Study of Africa," Simon Gikandi[20] stresses the need for multiple viewpoints and cultural ideas when studying African modernities. He suggests rethinking modernity outside the European context, acknowledging its ties to the European Enlightenment, and recognising the tensions that arise when adapting modern principles in African art, teaching, architecture, and urbanism. Through analysing African literature, Gikandi examines the interplay between embracing modernity and preserving Africa's rich cultural legacy. In **Fig. 3** Uche Okeke's visualisations depict scenes from the novel Things Fall Apart. They provide

an initial understanding spatially speaking, of how Africa, and Nigerian modernity can be expressed through African literature below:

Thus, modernist architecture, focusing on efficiency and rationality, often clashes with the social and cultural realities of African cities. Lindsay Bremner highlights this conflict by noting that modernist planning, synonymous with the modern state, coexists with

> *insurgent citizenship practices. These practices parody, empower or subvert state agendas, embodying struggles over modern society membership. Bremner's analysis shows two modes of planning—modern and insurgent—as antagonistic yet complementary paradigms. Both authors advocate for a nuanced view of African modernism.*[21]

Gikandi, more assertively, suggests these paradigms should coexist, akin to a shop within a shop, capturing narratives of lived experiences. He argues that modernist African writers like Chinua Achebe use storytelling (ethnographic and anthropological tools) to bridge the gap between African identities and modernity. Achebe's "Things Fall Apart"[22] and "No Longer at Ease"[23] explore societal transformation under colonialism and the pursuit of modernity, showing the effects on Igbo culture and the balance between traditional values and modern influences. Gikandi claims that Achebe's approach offers a dynamic blend of modernity rather than a mere replica of Western modernity. Ngugi wa Thiong'o supports this, emphasising that language transmits cultural values.[24] This paper argues that spatial manifestation through language carries cultural belief systems from precolonial times, and when these cultures coexist, they insert variety into modernist architectural practices. Bremner describes these as *"insurgent practices"*[25] that introduce new identities and practices, creating a dynamic ethnographic rather than utopian city. Gikandi's exploration of African literature posits that these narratives offer insights into African modernity, demonstrating a blend of Modernist ideals and what constitutes a particular African identity. The interplay of Modernist ideals and what constitutes a particular African identity embody Homi Bhabha's Third Space Theory, where cultural identity is produced in the "*in-between*"[26] regions created by cultural interplay, resulting in a new hybrid identity. This Third Space challenges colonial dominance by deconstructing essentialist identities and binaries, allowing new concepts to emerge from cultural contacts. In conclusion, modernist African literature bridges the divide between modernity and cultural identities by emphasising real-life experiences and cultural legacies captured and written by Africans. This perspective underscores the need to integrate multiple cultural narratives into our understanding of modernity, especially in African architecture and urbanism. The following section on narrativity will provide tools for researchers to contextualise and write hybrid modernist practices into being.

4. NARRATIVITY: TOWARDS BETTER AFRICAN CITIES

Narrativity, essential to literature and discourse, also plays a crucial role in architecture and urbanism. It involves considering the story elements that

shape cities and their identities. Lindsay Bremner and Stephanie Newell provide insights into using narrativity to reimagine urban spaces. Bremner highlights writing and representation's significant role in shaping cities, particularly in Johannesburg, South Africa, emphasising the power of language in bringing a city into being and speaking to its future[27]. This approach underlines the impact of narrative in shaping urban realities, focusing on the transformative potential of narrativity in city planning and architecture. Stephanie Newell explores storytelling's power in addressing the remnants of colonialism and shaping African identity, pointing out that narratives can challenge dominant historical perspectives and celebrate African perspectives through a blend of realism, mythology, and history[28]. Works by Chinua Achebe, for example, challenge colonial narratives, by asserting precolonial African subjectivity and redefining cultural identities. In architecture, African modernist architecture reflects postcolonial identity, mirroring the narrative efforts to reshape cultural perceptions. The intersection of narrative and architecture serves as a medium of cultural expression, questioning established power dynamics and authentically expressing African identities. Bremner's focus on Johannesburg reflects on how residents, through their personal experiences, shape the city's evolving narrative, challenging traditional architectural notions. This approach emphasises observing and interpreting urban spaces to enhance understanding and reimagining of urban and architectural designs, recognising the importance of diverse narratives in discussing African urban research. Modernist architecture, often detached from specific cultural contexts, contrasts with narrative-driven approaches that prioritise lived experiences and identities. This narrative method acknowledges African urbanism's diversity and complexity, promoting a more inclusive and representative architectural practice. Listening to city inhabitants and their stories allows for a deeper understanding of urban dynamics and the potential for integrating modern architecture with African identities.

5. CONCLUSIONS:

Finally, the paper examines how modernist African literature uses numerous narratives to investigate diverse experiences. It examines how modernism in Johannesburg, South Africa, reflected colonial legacies and maintained racial spatiality. The study proposes that narrative in literature and understanding African cultural practices can change colonial legacies and contextualise modernist architecture in African towns. It uses Johannesburg's "shop within a shop" to demonstrate how identity narratives may lead to hybrid modernity and cultural diversity. The study also highlighted the role of African literature in examining African modernities and narratives and how stories can bridge African identities and modernities. The author claims that "Narratives-within-a-narration" in literature and architecture can resist abstract modernity and highlight African societies' lived experiences and cultural continuity. ■

ABSTRACT

Taking full advantage of Nnamdi Elleh's proposal, by seeking to "keep the focus on the modern" (2014), this article explores how during the late colonial period in the city of Luanda, Angola, conditions arose to link the future of architectures with unequal roots. On the one hand, an architecture strongly qualified and praised by the historiography of modern architecture, which would result in the Prenda Neighbourhood Unit No. 1, and on the other hand, the musseque (Angolan slum) of the same name, which already occupied that territory in the suburbs of the colonial city. Placed in the core of the musseque, the Neighbourhood Unit (NU) was used strategically by the colonial state to control African population. Through the embodying of "brutalist imaginaries", it would be permanently linked to a new landscape, strongly supported by self-produced architecture.

As a case study, the Prenda musseque not only preceded the new NU, but coexisted with its realisation and appropriation, surviving to this day. It thus provides multiple lenses for analysing how architecture promoted by the "underprivileged classes" can today contribute to broadening the architectural lexicon of production catalogued as modern. Drawing on multiple skills, the knowledge of the musseque communities was neglected by the late-modern colonisers who inhabited the new Prenda units. This article evokes the concept of "omnicompetence", explored by Glenn Adamson (2020) in the broader context of American crafts shaped by pre-colonial societies. Also in Luanda's musseques, a long formal and constructive genealogy has emerged as pluri-competences. Its long coexistence with modern culture during the colonial period and beyond was reinforced by its contemporary resilience reflected in the transfer of technical and formal knowledge creating a vernacular architecture with a strong modern tone. The article ends by highlighting how these architectures have mutually legitimised each other as "compagnons de route".

1. INTRODUCTION[1]

Architecture produced in Angola during the late colonial period (1961-1975) has been the subject of two different historiographical views. The first established the primacy of exceptional buildings, which set out the theses of the "tropical modern" as an offshoot of the canonical Modern Movement that dealt with climate.[2] The second, critically enunciated by the Social Sciences, has been questioning how these enterprises reinforced racial segregation, using tools such as zoning, associated with the Athens Charter.[3] Luanda and its 1961 Masterplan, based on Neighbourhood Units (NU), is today an example of this dual treatment.[4] The plan was launched in the beginning of the country's war of liberation,[5] by the Luanda City Council's Urbanisation Office, then headed by the architect Fernão Lopes Simões de Carvalho (Luanda, 1929). Outside the colonial history, Nnamdi Elleh proposed, in 2014, a new lens by describing the "architecture of the underprivileged classes" as an "architecture of modern affiliation".[6] Elleh's analysis allowed the focus to remain on modern culture, drawing attention to the fact that the contemporary city had emerged in parallel with the "shantytowns". Confirming the crucial value of studying these urban structures, Elleh adds that this architecture participated in concepts "we now call sustainable design".[7] Such a hypothesis would bring these self-built buildings closer to the idea of a "vernacular architecture" – particularly when following authors such as Linda Asquith and Marcel Vellinga[8] –, and thus contributing to a debate that reinforces the links between a historically defined production (the modern) and an ongoing practice with repercussions in contemporary times (the self-built).

1.1. MODERN EQUIVALENTS?

This paper contents for a narrative that links the two realities. Without disqualifying the modern heritage, it aims to explain how conditions were created in colonial Luanda to link the future of architectures with unequal backgrounds, observed from the musseque perspective. These conditions resulted from using the NU as an urban planning strategy. Placed in the core of large musseques, mainly to neutralise their structural logic and monumental scale, these NU embodied "brutalist imageries"[9] while becoming lastingly linked to a new landscape, heavily supported by self-produced architecture. As a case study, the Prenda musseque, not only preceded the new NU, but coexisted with their realisation and appropriation, surviving to this day (**Fig. 1**). It thus provides multiple lenses for analysing how the architecture self-promoted by the said "underprivileged classes" can today contribute to broadening the architectural lexicon of production catalogued as modern.

To move forward in this narrative, the idea of "omnicompetence," explored by historian Glenn Adamson offers a highly useful conceptual framework.[10] In the musseques, an extensive formal and constructive genealogy arguably emerged as a complex set of pluri-competences.[11] The long coexistence of this know-how with modern culture during the colonial period and beyond was reinforced by its contemporary resilience, to be seen in the transfer of technical and formal knowledge that created a vernacular

5. The Colonial/Liberation War in Angola lasted until the so-called April Revolution (25 April 1974),

architecture with a strong modern tone. Like true "compagnons de route," the architecture of the Angolan musseque echoes how late modern architecture survives, taking advantage of resources ignored in Western societies.

2. MUSSEQUE PRENDA

The Prenda musseque endures today as an urban structure that survived the colonial period and went through the Angolan civil war, which ended in 2002. The monograph published in 1968 by the geographer Ilídio do Amaral (Luanda 1926- Lisbon 2017) described the advance of the "planned" city over the self-built musseque. Amaral estimated that 180 000 inhabitants were precariously housed here.[12] Accommodating this population in formal housing seemed an impossible goal. The heterogeneity perceived by Amaral among inhabitants was manifested, in his opinion, in disruptive ways of inhabiting the urban territory, including syncretic religious practices, polygamy and marginalisation. This anathema stemmed from the process of "detribalisation" that worried the colonial authorities.[13] Amaral lamented that there had been no "spatial organisation in communities, in which the evolution of family life [could] be respected"[14]. Meantime, a large residential experiment was underway, planned for "about 4 500 inhabitants, encompassing three economic housing areas (collective, single-family and independent single-family)".[15] Amaral was describing one of the projects later most celebrated by the historiography: Unidade de Vizinhança Nº 1 do Bairro Prenda, by Carvalho with Luiz Taquelim da Cruz (1928-). The architecture was designed by Carvalho with José Pinto da Cunha (1921-1985) and Fernando Alfredo Pereira (1927-).[16] A new territory in transition simultaneously welcomed two architectures in a preview of the future: one considered qualified within the framework of the dominant culture and the other that exposed "the custom of clandestine construction, in transgression".[17]

2.1. PRENDA NEIGHBOURHOOD

The new NU[18] stood over the Prenda musseque, which in 1964 had a population of up to 13 000 inhabitants:[19] 3 368 African families cohabited with 215 settler families.[20] When outlining the housing strategy, the colonial services envisaged three different types of NU, combining ethnic origins with economic income.[21] Only the first type – of which there were ten – envisioned the presence of "white" population.[22] Four out of the six NU in the Prenda musseque belonged to this group.[23] The remaining two, aimed at the most disadvantaged population, were part of type III – overall the most numerous, with 17 proposals.[24] The new plan offered a diversity of residential occupations, from two-storey flats to high-rise blocks, designed by trained architects and placed on the property and rental market; to single-family housing under assisted self-building, partly financed by the authorities. In order to minimise public investment, some plots within Type I Units provided for the installation of prefabricated houses for the "economically weak" population.[25] One of these models had a very simple plan with a living room, two bedrooms and a bathroom, using wooden

which put an end to the dictatorial regime in Portugal and began the process of independence.

panelling, standardised windows and doors, and a gable roof (apparently) made of zinc. Amaral himself recorded some of these examples in 1964, probably in NU 2 of the Prenda neighbourhood (**Fig. 2**).[26] These houses were still part of an architecture designed for the underprivileged classes, incorporating "materials and tectonics that were derived from the location in response to the vernacular methods of construction".[27] The quality was technically and aesthetically inferior when compared to ancestral typologies such as the traditional axiluanda house on Luanda Island.[28] The fact that these prefabricated houses were open to self-produced improvements showed confidence in the local entrepreneurship.

These built endeavours were one step ahead of an even more "marginalised" population, who, according to the geographer, built "poor housing on the urban periphery, without the minimum of sanitary conditions and amenities, scattered chaotically over the terrain and forming relatively dense agglomerations".[29]

3. SUBURBAN VERNACULAR HOUSE

The ethnographer José Redinha (1905-1983) also considered "suburban housing" to be one of the "biggest problems on the fringes of Angola's large cities".[30] In 1964, he summarized the traditional housing in Angola by describing the musseque as the place of the "last cycle of the native house," both detribalised and suburban.[31] In Luanda, such dwellings were generally a "plastered wattle and daub (pau-a-pique) house, with galvanised iron sheeting on the roof".[32] The publication also covered the so-called "modern phase," presented as an alternative to the decline of "ethnic building types". The rectangular and slightly raised floor plan, the increased number of openings and the defined courtyard emerged as the result of new modes of "acculturation".[33] The sense of permanence and the presence of the backyard figured as an introduction to urban life that broke with tribal tradition, both in terms of nomadic experiences and the sense of ownership. His study established a standard form of housing for the musseque, which he called a "backyard house (casa-quintal)", functional and in a single-storey, without being completely closed off from the outside. Finally, the "associated use of definitive materials and still valid native resources would mark…the limit of the evolution of the suburban house".[34] The process was thought to naturally lead to the assimilation of the traditional house by the modern one. Meantime, the building skills of African populations had to be harnessed to lighten the housing shortage. The building capacity revealed by the musseque populations was interpreted as a transitory resource and an economic measure, since the "future evolution of the 'habitat' to higher levels" was believed in.[35]

3.1. MRS E. AND MR B.'S WOODEN HOUSE

The introduction of prefabricated wooden units during the late colonial period has yet to be studied. These houses spread to different areas of Luanda (Ilha de Luanda, Praça da Madeira and Bairro Operário[36]). On 17

November 2014, a couple living in one of these houses was interviewed to trace the history of the transformation of the accommodation.[37] Their testimony confirmed much of the information contained in Amaral's monograph. E., aged 58 at the time, and B. came from the Gabela region, about 400 kilometres from Luanda, having met in the capital, where they arrived in the 1960s. They belonged to the 60% of the city's non-native population living in the musseques mapped by Amaral.[38] Before settling in Prenda, they had independent life paths, having lived in different areas of the city, depending on their professional situation.[39] Settling in the latter neighbourhood was due to family ties. The accommodation that E. lived in between 1967 and 1970, in the context of an extended family, was part of the group of "houses made of wattle and daub" that were rented out. In 1971, after marrying B., they rented a wooden house. Three years later they moved into their (then) current home. The original house, referred as the "motherhouse (casa-mãe)," was built in a rectangle measuring around 10,50 x 3,00 metres, with an interior ceiling height of 2,56 metres and a gable roof. The doors were 1,86 metres high, and the original windows measured 0,62 x 0,82 metres. At the time of the interview, the household gathered 16 people linked by various kinship ties. The family growth had required successive extensions to the configuration of the house, totalling nine bedrooms and six bathrooms, in addition to the living room and kitchen. Two thirds of the wooden house survived and only one of the bedrooms was extended. The original building material was replaced with cement blocks. The "new" house was given an L-shaped layout. The initial backyard-house was gradually replaced by a courtyard-house. This transformation boosted a feeling of "greater security" according to the testimony collected. The biggest problems were still sanitary, namely difficulties in accessing piped water and interruptions to the electricity supply. Photographs reinforced these shortcomings while underlining the presence of a very strong outdoor experience (**Fig. 3**).

4. CONCLUSIONS: COMPAGNONS DE ROUTE

The article shows that the Prenda NU No. 1, the prefabricated wooden houses, and the self-built houses of the musseque Prenda, in Luanda, are part of different lineages within the architectural culture of the 1960s, with repercussions in the present. It can be argued that the first derives from a modern erudite effort; the second crosses local functionalities with industrial systems, and finally the third stems directly from vernacular culture. Some experts within the colonial apparatus, such as José Redinha, mentioned in the article, suggested that the vernacular settings were condemned to being replaced by more "qualified" buildings through the Western lens. However, their resistance to the different typological, constructive and aesthetic solutions introduced at the time, and even further promoted after the independence of Angola, showed how hasty the verdict of its disappearance had been. The buildings' ability to adapt through climate-proofing and construction techniques from modern architecture demonstrated how the

boundaries between erudite and vernacular principles had been blurred over decades of architectural appropriation. The wooden house inhabited by Mrs E. and Mr B., pictured as a case study, was built at the end of Portuguese colonialism as an economic solution for the underprivileged classes. Its growing appropriation has since revealed an openness to transformations using local technical know-how, which means that it persists today in the Luandan landscape as a self production work. It is due to the consolidation of these different architectural models throughout the history of the Prenda musseque that they can be approached as "compagnons de route". The current musseque is thus a collection of housing experiences that evoke the history of recent architecture while also displaying work-in progress examples. ■

ABSTRACT

The natural house ideas return to the primordial notion of shelter, from its material, technical, and energetic conditions to its social conditions, as well as phenomenological, existentialist, and even ecological conditions. Indeed, it is essential to contextualise the "natural house" within the framework of "urban designs" for a modern city historically committed to re-establishing a balance between the countryside and the urban environment[1].

Some current reconsiderations of modern architecture and urbanism, especially from an environmental point of view, often criticise the limited sustainability inherent in its guiding principles. Nevertheless, modern architecture was prolific in urban projects related to nature and technical devices for its management, both in form and in relation to the land. Typological research to establish this relationship was also extensive and diverse. When it comes to exploring and developing new ideas for the future of a sustainable built environment based on the past experiences of the Modern Movement, the critical points lie in the relationship between building and nature in a more realistic and practical term and on a theoretical effort to work on the distance between the idea of the natural house and the environmental design - as a cultural sphere - to face the artificial condition of the generation of the city.

1. THE NATURAL HOUSE

At the end of his long career as an architectural historian, Christian Norberg-Schulz (1926-2000) summarised what he considered the fundamental paradigms of modernism in his book Principles of Modern Architecture.[2] Among these paradigms, he notably included the concept of the "natural house," a proposition that may evoke surprise in contemporary discourse. Indeed, present-day reconsiderations of modernist architecture and urbanism, particularly from an environmental standpoint, often cast a critical eye upon the limited sustainability inherent in its guiding principles. Such reassessments frequently manifest as overtly anachronistic value judgments. This is attested to by the analysis of the origins of the principle of the "natural house," a notion that is certainly complex in the reading postulated by Norberg-Schulz, particularly in its interplay with the precepts of modern urbanism. Understanding the cultural significance of models such as the garden cities or early twentieth-century social housing districts requires an appreciation of their explicit aspiration to harmonise biological imperatives with social practices—bridging the realms of natural environment and modern culture.

Norberg-Schulz adopted the term "The Natural House" from Frank Lloyd Wright's book of the same title, published in 1954[3]. It elucidated the meaning of his "organic architecture" as applied to the design of individual homes, in which a return to the primordial notion of shelter, from its material, technical and energetic conditions to its social conditions, was intended. In short, the house was considered a totality that constitutes an order of things and thus establishes and represents a world (both a tangible microcosm and an *imago mundi*). For instance, Wright's houses often featured elements like fireplaces and hearths, symbolising the forces of nature, centrally positioned within the architectural design. Additionally, Norberg-Schulz observed parallels between Wright's organic Prairie and Usonian Houses and the cottages of the Arts & Crafts and the Jugendstil-houses, or Central European and Nordic modernist houses, since they all expressed a common desire for a new "natural life." This modern condition is rooted in their promise of plenitude.

To understand correctly the scope of the "natural house" principle postulated by Norberg-Schulz, it is worth bearing in mind that, contrary to what his Norwegian origin and the fact that most of his academic activity took place in Oslo might suggest, his was not a peripheral protagonist, nor were his interpretations of modern architecture conceptually marginal. On the contrary, his concept is rooted in the central traditions of modernity. He studied architecture at the ETH Zurich, where he was a student of art historian Sigfried Giedion, responsible for several modern architecture canonical histories. He had already participated in the first CIAM in La Sarraz (1928) and was, for a long time, the secretary of this somewhat sectarian lobby of modern architects. As early as 1949, Giedion urged Norberg-Schulz to establish a Norwegian CIAM group. As Eric Mumford has studied, he went further and assumed the leadership of the "youth members" when, in 1952, the "CIAM Council Meeting" was held in Sigtuna (Sweden).[4] There, the generational renewal of CIAM began, with young protagonists who would

later constitute Team 10. The debate on the concepts of "habitat" *versus* "dwelling" as the guiding principle of modernity is an example of the thematic renewal that the arrival of this new generation implied. This turn marked a departure from the debates developed at CIAM 8 (Hoddesdon 1951) around the concept of "The Heart of the City."[5] On that occasion, Josep Lluís Sert had opened the congress with a lecture in which he quoted a famous passage from the book *The Revolt of the Masses* (1929) by the philosopher José Ortega y Gasset[6], who had interpreted the origin of the civic space of the *agora* in the Greek polis as a radical opposition to nature.[7] This revolutionary public sphere seemed to be radically different from the geo-botanical cosmos that had characterised the life of humans in their cohabitation with plants and animals. In Ortega's view, the vegetative space of nature did, however, endure in the familiar sphere of the home.

The book *Can Our Cities Survive?* (1942), which until then had been Sert's main theoretical contribution to the CIAM debates, disproves that Ortega's radical opposition to civic space and natural space was a central concept of modern architecture and urbanism. For example, he was evident when he advocated reconsidering the importance of "urban biology": "In its academic and traditional sense, city planning has become obsolete. In its place must be substituted urban biology, or the study of the life of cities and the living conditions within them."[8] Other recurring concepts in the book, such as "environmental control", "healthful environment", the inalienable "exposure to the sun and the natural surroundings", or the question "how can the week-end exodus be organised?" make it clear that the forms of social life in the modern city advocated by Sert were posing a renewed relationship with the urban environment and nature. Hence, Sert's relevance to the new regional plans is in his "total view of the city."[9]

It is striking that two decades later, Norberg-Schulz still referred to Sert's book in the introduction to his *Intentions in Architecture*[10], in which he attempted to offer a comprehensive theory of architecture. He was accompanied by other notable names of the time, such as Giedion or Lewis Mumford, with his *The Culture of Cities*.[11] However, among the sources cited, Norberg-Schulz included other names that gave an account of a conceptual renewal of the relationship between nature and modern architecture. For example, he included Tomás Maldonado in the list of acknowledgements: he had met him during Norberg-Schulz's teaching activity at the Hochschule für Gestaltung in Ulm, where Maldonado introduced systemic approaches such as those of cybernetics and semiotics into teaching and research. These, too, shared an integral scope that would culminate in the notion of an "environmental design," with which Maldonado was extraordinarily influential around 1970 among architects who were early involved in environmentalism.[12] However, Maldonado's notions focused on the "human environment" considered as the cultural sphere of the set of artefacts that make up an artificial system, an idea certainly far removed from a primordial nature.

In this sense, we can see that in Norberg-Schulz's principle of the "natural house", elements are entirely alien to the technical culture of

Maldonado's systemic "environmental design" postulated. The difference concerning Norberg-Schulz's theories' phenomenological, existentialist and even ecological elements is notorious. These are the focus of his two best-known books: *Existence, Space & Architecture* and *Genius Loci. Towards a Phenomenology of Architecture Towards a Phenomenology of Architecture*. In this existential consideration of the "good place," the notion of nature put forward by Norberg-Schulz drew on sources such as the writings of the philosopher Martin Heidegger, in particular his famous lecture "Bauen Wohnen Denken" (Building Dwelling Thinking).[13] Without this reference, it would be difficult to understand the capacity that Norberg-Schulz attributes to the domestic sphere to constitute a world or a microcosm, which in the case of the modern "natural house" would be evident in the way in which it opposes the experience of uprootedness characteristic of the modern world.

2. URBAN DESIGN AND NATURE IN THE MODERN CITY

One of the keys to the notion of the natural house was - in addition to its homely self-absorption - its direct and open relationship with nature. The microcosm of the domestic sphere was to leave behind representational forms and become natural again, with direct contact between inside and outside and with natural materials.

Both dimensions are underdebate. One, in the face of establishing not only an individual world of one's own but with others on a communal level. The other is the increasing absence of nature in the urban world. There is no shortage of city designs in modern architecture that sought to give nature a role. The 1930s were prolific in proposals from very different sides. **(Fig. 1)**

On the one hand, one can review the low-density proposals, from the initial recognition of the garden cities, which nourished the experience of housing in Frankfurt[14], to the more radical and individualistic vision of Broadacre,[15] which, although based on the idea of the natural house, proposed an infinite expansion of the urban phenomenon on the condition of the natural territory. The exercises of the Bauhaus students in the workshop developed by Hilberseimer[16], whose central motif was the study of L-shaped houses in the framework of a possible expansion of the natural territory, can also be noted here.

On the other hand, the proposals sought greater density, and nature appeared as a theoretical mantle on which to arrange the pure forms of rational aggregation. The reference to Le Corbusier's Ville Radieuse is evident, in which the buildings *à redents* were oriented according to helio-thermal axes and were displaced, leaving green spaces to incorporate public facilities.[17] Wladimiro Acosta's City Block[18] not only assumed the urban form of the traditional city but was conceived in direct relation to the green void. Richard Neutra's proposal, Rush City Reformed, where the population was distributed in residential neighbourhoods by age regarding primary education requirements, assigning community value to the smaller portions and green space a dominant value.[19] **(Fig. 2)**

A superlative advance had the notion in the debates of the APAO (Associazione per una architectura organica), in Metron and Comunittá[20],

placing itself on another more humanist ideological plane in the full intention of overcoming the individualistic restrictions of the notion of the natural house and the necessary community setting.

3. TECHNICAL DEVICES AND URBAN DESIGN

Modern architecture has developed many technical devices that relate to nature. Some were directly associated with the climate, such as the Helios-system, the brise-soleil, and ventilated walls with openwork bricks. The terrace, the roof garden, or the recovery of the central courtyard advanced the spatial and typological conformation of the units.

However, a more structural dimension at the level of urban design was necessary. The relationship between density and land use became clear early on. Several technical devices emerged from the rational ways of defining the relationship with nature, based mainly on the climatic suitability of the position of the architectural work on the ground and the relationship with the orchard or garden.

The rational spacing diagrams of the housing blocks according to the solar exposure of the façades offered free land for cultivation. The urban fabric forms generally assumed typological mixtures between blocks and houses, and later towers, in larger complexes. The *'a redant'* building or the *L-shaped house*[21] constituted typological possibilities concerning nature. Still, none of them assumed a more definitive status, both in theory and in urban design practice. **(Fig. 3)**

Sustainability proposes some essential modern technical devices worth reviewing for urban design. A myriad of environmental problems, such as rising urban temperatures, the inability to absorb water in urban territories, and the inability to maintain the green in the city due to the progressive disappearance of natural soil for planting, among others, puts the city's design at a crossroads.

Figure 3. Ludwig Hilberseimer. "L type house". In: Martin Wagner, *Das wachsende Haus. Ein Beitrag zur Lösung der städtischen Wohnungsfrage.* Berlin u. Leipzig, Deutsches Verlagshaus Bong & Co. 1932. Page 74.

Figure 4. Frei Otto, "Adaptable Buildings in a natural urban environment," from: **Mitteilungen der Entwicklungsstätte für den Leichtbau** (Berlin), nr. 6, 1959. Cover

Part of the problem seems to lie in aspects on which modern architecture and urbanism took a stand. On the one hand, the overall density of the city and its neighbourhoods and the occupation of land are concerning the voids. On the other hand, the problem of the size of the formal architectural aggregation to establish communities.

The first establishes a direct relationship with the proportion of nature in the urban environment, and the second refers to the possibilities of constituting communities beyond the individual domestic sphere. It seems necessary to bring back to the fore the notions of the density of the built-on natural ground and the urban community. Just as Frei Otto could have imagined it in 1959. **(Fig. 4)**

In 2001, Duncan Lewis - in a text that has taken on unusual validity - predicted that "the city of the future will be denser, and nature will be more present". [22] He proposed, in the face of the excessive urbanisation of the territory, "another type of natural contract" and the replacement of the architecture-city binomial with that of architecture and nature.

Lewis argued that *"It is necessary to create a new culture where natural areas and human density can be developed together to respond to real needs and values. In this framework, architecture could reduce its artificiality and finally consider a relationship approximating its environment. But it is necessary that by environment, we understand its meaning in the broadest sense, i.e. essentially urban and social, and despite everything technical. It is not just a question of building huts in the forest, of adopting an anachronistic and marginal attitude, but of responding to a constant and legitimate desire and aspirations by participating in an omnipresent reality."* [23]

The urban project can no longer assume the escape into the individualistic microcosm of the suburban house; it is essential to shape another city. When it comes to exploring and developing new ideas for the future of a sustainable built environment based on the past experiences of the Modern Movement, it is not only about revisiting the experience of neighbourhood construction. One of the keys lies in that relationship between building and nature in a more realistic and practical term, and on the other hand, a theoretical effort to work the distance between the idea of the natural house and the environmental design - as a cultural sphere - to face the artificial condition of the generation of the city itself. ■

THE GROWING CITY. THE HYBRID CHARACTER OF NATURE IN SCHWAGENSCHEIDT'S *RAUMSTADT* CONCEPT

MORAN LEV
KIT, KARLSRUHE INSTITUTE OF TECHNOLOGY, FACULTY OF ARCHITECTURE, CHAIR FOR INTERNATIONAL URBAN PLANNING AND DESIGN (ISTB) IN COOPERATION WITH THE POST-WAR MODERNIST HOUSING RESEARCH LAB AT THE FRANKFURT UNIVERSITY OF APPLIED SCIENCES

#12

ABSTRACT

The paper emphasizes the importance of generating a new approach toward analysing and conceptually understanding post-war modernist housing within the discussion of *hybridity*. The main argument of the paper is that by discussing *hybridity* as an action with its dynamic qualities (rather than its static, permanent ones), we are revealing one of the term's core intentions, namely, the ability to change and allow the users of the space to act and react as an essential part of continuous development. To do that, Norberg-Schultz´s modern architecture principle of the *Natural House* is being used as a benchmark to discuss the urban design approach of the Nordweststadt, one of Frankfurt/Main's most ambitious post-war modernist housing projects. Reflecting on Walter Schwagenscheidt´s *Raumstadt* concept, corresponding approaches are explored to discover the social-spatial anchors of *hybridity* embodied in the envisioned and lived spaces characteristic of the post-war housing projects. Schwagenscheidt´s perception of nature as a form of unity between private life, social infrastructure, and the public realm strengthens the argument that nature plays a significant role in the open-system layout of the Nordweststadt, providing a platform for the possible expansion of the project and enhancing the participation of the residents in that process. Through a critical reflection on the potential embodied in becoming natural again, the paper aspires to expand the understanding of the term *hybridity* in the context of modernist housing projects to the social and the in-between one, seeking eventually to show the uniqueness and adequateness of post-war modernist housing as a social-spatial and cultural source. The aspired insights of the research could help position similar housing projects as additional experimental fields for the realization of new interpretations of the concept of hybridity as a development process.

1. INTRODUCTION

"What then is the point of forcing the layout into a rigid, inflexible system? Instead of constantly reshaping it!" (Schwagenscheidt 1964, 39)

The *Raumstadt*[1] concept that the German architect Walter Schwagenscheidt (1886-1968) started working on during the third decade of the last century went through several development stages before being finely manifested in form with the building of the Nordweststadt in Frankfurt/Main, a project he and his office's partner, the architect Tasillo Sittmann (1928-2022), were commissioned with between 1959 and 1968. Although some aspects of the concept underwent spatial changes throughout the years, its core ideas stayed untouched: The *Raumstadt* offers an open-plan system for a new kind of residents—a new urbanity of possibilities tailored to the "open, democratic, and pluralistic society" that would inhabit it (Preusler 1985, 17). The first ideas at the core of the concept were aimed at achieving simple and intelligent solutions for men's lives in cities after the First World War, and nature played such a significant role in the first evolutionary steps of the vision that the houses and people were barely seen in the first concept sketches made by Schwagenscheidt.

The reason that architecture plays just a minor role in this idea as opposed to nature also served Schwagenscheidt´s understanding that the green spaces in the quarter ought to offer both openness and a sense of security for the residents. This vision directly corresponds with Christian Norberg-Schulz's (1926-2000) definition of the *Natural House* as "[…] a new kind of informal living, in contact with natural materials, simple straightforward artefacts, and, if possible, a natural environment". In his book *Principles of Modern Architecture*, published shortly before his death, Norberg Schulz emphasizes the role of the house within its relation to the green and open spaces surrounding it as a place able to provide its inhabitants with the intimate feeling of "belonging and protection". And to Schwagenscheidt and Norberg-Schulz, a sense of belonging is much needed as we depart our house again and again (Norberg-Schulz 2000, 49). Furthermore, Norberg-Schulz's reflections on the houses' ability to provide their residents with a sense of rootedness echoes Schwagenscheidt´s idea of participation and loyalty that the residents of the city should be feeling through the use of nature as it spreads between the buildings of the city.

By creating a dialogue between Norberg-Schulz´s modern principles definitions and Schwagenscheidt's planning concepts, the paper wishes to discuss interpretations and understandings of the term Hybridity as an urban agenda, one that understands that the urban assignment must seek to create a synthesis between the different being's manifestations, their spatial requirements, and their cultural and societal needs, allowing the built environment to develop according to changing human and societal demands.

Reading the *Natural House* and nature as places of "open interaction and simultaneous events," (Norberg-Schulz 2000, 50) shows that *hybridity*

1. The word Raumstadt in German combines two words: Raum = Space, room stadt = city. Therefore, the term can be translated into English as "Spatial City" (not to be mistaken for Yona Friedman´s Spatial City project from 1958).

can be read as a process that depends on the interpretation of the changing users and not just the functional or architectural setting. Furthermore, such readings can help us create a new understanding of *hybridity* as an action and reaction being adaptive and fault-tolerant urban agenda that can contribute enormously to the discourse regarding both the future of post-war modernist housing and the ability to reshape the public´s image of those projects; as while their cultural value is well appreciated, their current widespread image is one of "monotonous, grey, and impersonal" relics of the past (Harnack, Brunner, and Heger 2020, 4).

2. HUMANITY, URBANITY, COMMUNITY: FROM THE NATURE CITY TO THE GROWING ONE

When Schwagenscheidt developed his ideas about the *Nature City* (*Naturstadt*), which then became the *Raum-* and *Wohnstadt*, Le-Corbusier's ideas about the *Machine for Living* (*Wohnmaschine*) also took shape. For both architects, nature played a significant role in the design. Furthermore, both architects used the word "cell"[2] to describe the basic units and spatial proportions at the core of their ideas. To Schwagenscheidt, the cell was the basic unit constructing the city, clusters composed of several buildings and arranged together around a joint court **(Fig. 1)**. Nature played an elementary role in those clusters' composition, and life was formed by and around it.

Schwagenscheidt titled his concepts differently through the years, but the characteristics of the natural spaces remained the same. From the beginning in the twenties (1920-1923) with the drawings titled *Outside Space* (*Außenraum*), all the way to the sketches done more than forty years later of the courts and open squares in the Nordweststadt. Those spaces were always "spatial creations" that modelled the "ideal of introversion of a centered place that can be experienced and lived through residing" in them (Gleiniger 1995, 153f). Moreover, the head of the planning department in Frankfurt/ Main back then, Hans Kampffmeyer Jr. (1912-1996), shared this social intention of shaping life in the city anew through the urban design composition of living cells and nature. In his book, published shortly before the complete realization of the new city quarter, Kampffmeyer emphasizes that the " […] humane and truthful city planning visions for them, the name Schwagenscheidt stands for, were especially attributed to the planning of the green areas, as those living green (*Wohngrün*) should fulfill their function in shaping the society" (Kampffmeyer 1968, 62).

Corbusier´s design homogeneity of the *Machine for Living* suggests, in a way, an abolishment of the differences between classes: All cells (buildings) look the same, and all apartments look the same. In his concept, workers, doctors, and university professors live together in one cell. These social ideas are just as present in Schwagenscheidt´s ideas of living: The cells building the Raumstadt are composed of different buildings, which aim to gather around one court, the doctors living in their houses with

2. Cell in the context of Corbusier´s *Machine for Living* and Schwagenscheidt´s *Wohnstadt* is to be understood as a spatial reference (=a small unit) and not in relation to biology.

the workers, or single-parent families living in one of the apartments of the high-rise buildings. With the change of title, Schwagenscheidt then diverted the focus of his concepts from nature toward the residents and users of the envisioned spaces', giving them a chance to intervene in nature and modify their living environment. Moreover, nature systematically came to his aid in this conscious decision to place people at the concept's center and give them an active role in shaping and re-shaping their living environment (Preusler 1985, 44). Nature was then given an extra role as the platform for neighborhood life. This idea will be further emphasized as Schwagenscheidt starts formulating his *Growing City* (*Die wachsende Stadt*) concept. Again, by diverting the focus from the built to the unbuilt, Schwagenscheidt made another achievement: Giving the residents an intermediate space that could be changed upon, extracted from, or further completed. Furthermore, though the playing field should be clearly defined, the game's rules are left to the players. Schwagenscheidt wanted the spaces to have a clear and definite form that would be kept despite the possible additions or subtractions done by the residents´ intervention (Preusler 1985, 45).

He was unequivocal regarding both the physical borders of intervention and his professional borders as an architect. The residents' interventions are not supposed to make the city bigger; they are just supposed to make it more suitable to their requirements and changing needs: "Each family has its own little plot of land. On it, they can build what they wish. They extend or reduce their house as may prove necessary" (Schwagenscheidt 1957, 107). Since the people living in the city can participate in designing their neighbourhoods and quarters, he stressed that the architect is not the main focus when designing the space but rather the person who is supposed to live in it (Preusler 1985, 50).

The conceptualization of the idea of the *Growing City* took shape mostly during his years of practice in the USSR, and it originated from his observation of the working and living conditions of both those workers contracted with raising the new cities in Russia and those who were supposed to be populating them. For him, here lies the opportunity to help those parts of the population that belong to the "lower cultural levels" to have the possibility to live and change their environment into a "paradise city", which in turn, as he was convinced, "should contribute to the development of the people" as they take part in its realization gradually till it becomes its beautiful end form (Preusler 1985, 104). With this idea, Schwagenscheidt strived to develop an urban design approach to benefit the life of the "millions of helpless comrades yearning for air and son" (Preusler 1985, 107). The uniqueness of the concept lies not just in its high aspirations to build a living environment that allows its residents to modify it further as they wish. Just as attractive are the social, ecological, and economic qualities of the idea as it calls for the design of worker's barracks with a flexible layout that will be constantly changeable in their inner spaces as the building of the city progresses and the number of workers

changes. The barracks take form; the inner spaces are modified, becoming more communal, until they arrive at their final stage, where the barracks are transformed into individual apartments. Then, the focus is diverted back toward the outside areas between the buildings, and nature captures his role at the stage´s center again as the space that brings it all together and forms the city **(Fig. 2)**.

Schwagenscheidt's enthusiasm about the necessity of the direct connection between men and nature resulted in the idea that a city could temporarily even function without sewage canalization during its construction. For him, a one-story building has a natural connection with its garden and with the earth, and in a city based on such a concept, one can even spare the canalization since the human excrement can be directly used as compost for the earth. With this concept, Schwagenscheidt advocates for a city's planning without the necessary canalization infrastructure or high-rise dwellings, claiming that the urban landscape with low-rise buildings gives nature its ability to express itself fully (Schwagenscheidt 1949, 20).

Through the many drawings produced over the years to explain his urban ideas, Schwagenscheidt was determined to transfer an atmosphere rather than present a spatial organization. Seeking a way to capture the *genius loci* of his cities, he first created nature scenes and later moved on to present urbanity through staging daily sceneries of street life and neighborhood gatherings full of people of all ages and occupations, described in such detail that one can start understanding their character **(Fig. 3)**. Either way, it was always the ambition to capture the feeling of the possible inter-relationships that will occur in the spaces he creates, whether between men themselves or men and nature. To that extent, both Norberg-Schulz and Schwagenscheidt identified nature as a completion of the private sphere, claiming that the outside natural space is the extension of the house and the spatial tool to let us, as individuals, engage in society.

3. THE DIFFERENT NOTIONS OF HYBRIDITY

The current literature on *hybridity* as an architectural form or urban agenda can be roughly divided into four main themes: Functional, spatial, social and cultural, and processual hybridity. Though Schwagenscheidt´s *Raumstadt* concept offers some insights regarding the possible functional hybridity within his budlings, it is the potential processual hybridity that mostly resonates in his ideas. The informal character of space and the planner's intention to provide the future residents of his city the ability to adjust and readjust the built spaces to their demands reflects the necessity of the modern house to allow "the world of private, circumstantial life" to be visible (Norberg-Schulz 2000, 59). With the growing, adaptable city, Schwagenscheidt was also criticizing "[…] our cities [which] suffer from the fact that they are rigid as if they were built to last". Schwagenscheidt aimed to create a "natural city […] with all modern technical achievements". He claimed that "life continues to change [and]

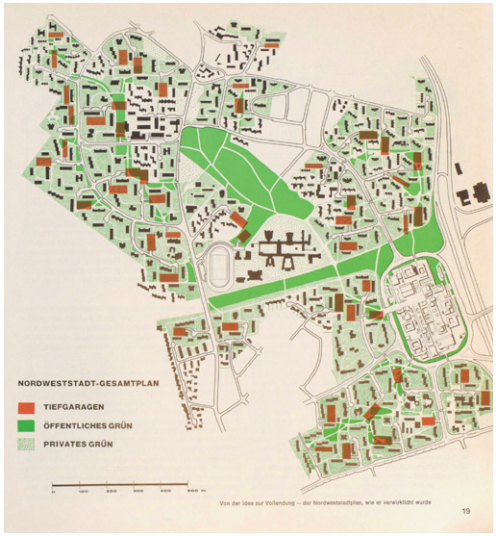

Figure 1. Plan of the Nordweststadt with the location of the underground parking lots (orange), the public (green) and private (dotted green) green spaces, 1968 © (Kampffmeyer 1968, 19)

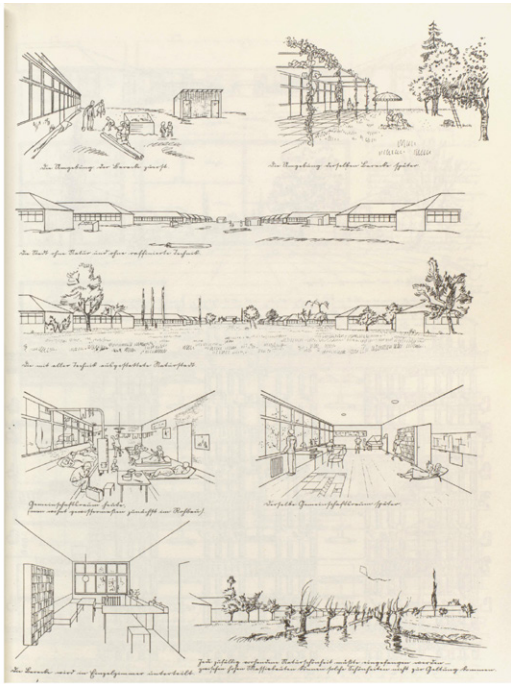

Figure 2. The Growing City, Realization stages, 1933 © (Schwagenscheidt 1949, 21)

that is why the cities no longer suit today's people. Hence [the solution is] the growing, lively, ever-developing city that easily adapts to new conditions!" (Schwagenscheidt 1949, 22).

The suggested interpretation of Schwagenscheidt´s *Raumstadt* concept as such of offering room for the processual hybridity to take place echoes Louis Kahn´s (1901-1974) urban ideas of "in-commonness" as an intention to create spaces that invite the people to experience and participate in their living city. For Kahn, connectivity is one of the planner's most significant assignments. The connectivity he refers to is not of "[…] going from place to place" but one which can create places, "areas which are treated as events in the plan and which give a feeling of connecting one thing to another, a feeling of belonging to everything in the city" (Kahn and Twombly 2003, 120f).

In 1969, Louis Kahn was a jury committee member responsible for selecting 13 international urban design projects to be presented at the UIA (International Union of Architects) World Congress of Architects in Buenos Aires. The Nordweststadt was the only German project selected to be discussed, and Tassilo Sittmann was able to present the project in Argentina. Four years later, on May 10th, 1973, the two Architects met again to stroll through the green parks of the Nordweststadt. While admiring the urban design concept of the quarter, Kahn criticized the "not adequate" realization of the dwelling building, implying that they do not suit the high quality of the urban planning concept (Gleiniger 1995, 151).

Norberg-Schulz concluded his book about the principles of modern architecture, claiming that modern life in the city is about having a "[…] sense of belonging and meaning […] and meaningful existence presupposes a meaningful place which is commonly shared" (Norberg-Schulz 2000, 113). Feeling loyal to the city and belonging in your living environment through nature was a repeated theme in the texts by Schwagenscheidt. The interaction with nature in the Nordweststadt nowadays is accomplished through both the overwhelming way in which one feels that one lives in a forest of trees and buildings and through the way that nature serves as a natural backbone for the layout of the pedestrian paths infrastructure, connecting not just the different public centers with each other but leading the way also between one dwelling cluster and then another. Examining the models made by Schwagenschedit and Sittmann for the competition, we can also understand the hierarchal differentiation of those spaces and how it strengthened the urban design concept. Unfortunately, this vital design approach was not realized as envisioned by its creators.

4. BETWEEN EARTH AND SKY: CONCLUSION

The paper aimed to show nature´s role in the urban concepts envisioned by Schwagenscheidt, which were modified and then implemented in the realization of Nordweststadt. The fact that his social and spatial intentions stayed mostly unrealized utopias might be because the realization of the project was done under the supervision of the architects but according to construction plans composed by the three public building companies commissioned by the city. What remains clear is that the "principle of "openness"", both socially and spatially, is "unmistakably embedded in Schwagenscheidt's design" (Gleiniger 1995, 152), and this openness allows us to interpret and envision nature in the Nordweststadt and other post-war modernist housing projects as a potential hybrid field for future adaptation.

The city's ability to adapt is another concept that Norberg-Schulz briefly touches, saying that to "reveal how things could be, means to add something they are "lacking". A lack, however, is not foreign to the thing, but rather something which belongs to its hidden nature […] It is what the situation lacks, which sets the historical process in motion, and makes ever

new interpretations necessary" (Norberg-Schulz 2000, 115). For Norberg-Schulz, architecture's role was to complete the "lacking" between earth and sky and to transfer sites into places. For Schwagenscheidt, in my opinion, it was the role of the men and women, children and elderly, who lived between the earth and sky, to turn their living spaces into places of participation and new cities awaiting ever-new interpretations. As Louis Kahn wrote, hybridity's spatial expression should include the aspirations of that which it cannot express. This aspiration must "resort to measurable means; it must resort to nature of nature, which deals with completely measurable things". According to that, hybridity is, therefore, "a beginning – it is not a continuation – of something that is there, but something which gives direction and almost immediate participation to all" (Kahn and Twombly 2003, 76f). Perhaps, by revealing some aspects of the design concept of Schwagenscheidt anew, we can finally give its *hybridity* notions a beginning and immediate direction of fulfilment. ■

Moran Lev is an architect, urban planner, and PhD candidate at KIT, Karlsruhe Institute of Technology. He obtained a professional background in planning offices in Germany and abroad. He is currently a research assistant at KIT in the Chair for International Urban Planning and Design and at the Frankfurt University of Applied Sciences, where he is also a member of the Post-War Modernist Housing Research Lab.

FROM EDEN TO BABYLON. THE ROLE OF NATURE IN LIMA'S NEIGHBOURHOOD UNITS

SHARIF S. KAHATT

#12

ABSTRACT

Soon after the end of WWII, architects in Lima were vividly debating the urgency of planning the city's growth. The discussion was centered on the idea of Neighbourhood Unit which condensed and incarnated many different social, cultural, economic, architectural, and urban design ideals of that period. Responding to the need to provide mass housing and large-scale green areas in Lima, the concept *Unidad Vecinal* became the main design and planning instrument for the renovation and expansion of the city. This urban development provided a variety of housing typologies, traffic separation, open green areas, recreational and educational infrastructure, commercial spaces, and sports facilities. The essential principles of this concept were thought to organize the growth of the cities and had to provide good living conditions to all residents. In order to achieve that challenge, "nature" played different roles: in the first projects nature had a fundamental role of holding the architecture and give quality to the urban project, and later on, in the last projects, nature was placed within architecture to ensure good living conditions to the urban projects.

This paper will study two cases of Neighbourhood Units in Lima, the first built between 1945 and 1949 and the second around 1968 and 1975. In the first case, architecture was placed in the middle of agricultural lands and projecting a "natural Eden-like" context. In the second case, architecture was placed in the arid city's outskirts and deployed vegetation and green areas in some specific places —as Babylon Gardens did— to represent "nature" and enhance the urban spaces. In this sense, Unidad Vecinal 3 (1946) and PREVI Lima (1969), not only stand out for being the most ambitious, and coherent examples of each 'moment', but also, because they presented different roles of nature incarnated in the same urban design concept.

The 1940s and 1950s witnessed a surge in collective housing, becoming synonymous with urban planning. Large-scale housing projects were designed following the concept of the "neighborhood unit" and with several variations, encompassing modern designs and even self-help initiatives in Latin America. However, the following two decades (1960s and 1970s) saw a shift in the architectural discourse. The focus moved from housing projects as mere clusters of units within a master plan to the importance of the urban fabric and public spaces. This realization, initially seen in European cities, emphasized the role of public spaces in fostering a sense of community. It quickly gained traction worldwide, dominating international architectural discussions throughout those decades.

In this way, the dominant ideas in the ways of conceiving architecture and the city have been evolving over the decades, but they always return to the central theme of the discipline: the form of "inhabitation" in relation to the "nature", emphasizing the tension between *artifice and nature*, that is inescapable when designing new habitats. As pointed out by Norberg-Schulz —in relation to F.LL. Wright ideas[1]—, the "natural house" should allow people to be free and in close contact with nature, as a universal right. For Norberg-Schulz it was a paradox that the industrialized world had to create the desire for a 'natural' life[2], precisely, because its development made it evident that this social ideal has become a necessity for everyone and not only for a privileged group of people. The idea of modern architecture working towards that end of freedom and inner connection can be also found in the conception and development of the concept of Neighborhood Unit as a search for a 'natural environment' for an ideal life.

1. NATURAL HOUSE AND NATURAL ENVIRONMENT FOR MASS HOUSING

Continuing with the idea of the 'natural house', as Norberg-Schulz has pointed out, the search of modern architects (Mies van der Rohe or Le Corbusier) focused on finding spatial freedom and classical order from their first houses.[3] However, in those houses, modern architecture did not fully satisfy the idea of an actual "natural house" because they did not look like "houses".[4] That is, they did not offer to the families a recognizable image of a home. In this context, during the post-war decades, the image of modern housing became a recurring theme of debates, and, an object of criticism.

In the case of Peru, if we compare two paradigmatic Neighbourhood Units, —the official modern housing prototype— we can observe that while in the Unidad Vecinal 3 (UV3), the theme of the "natural house" with green areas suffers from the same problem as did the modern architecture (clearly influenced by the German Siedlungs from the Weimar Republic), whereas in the case of PREVI Lima, 25 years later, the challenge was resolved by designing single-family homes clusters, small-scale plazas and gardens, and different urban thresholds which were quickly appropriated by their residents by building additions, and giving them particular characteristics that made them easy recognizable as their homes.

In that line of efforts, Architect Fernando Belaunde reported in *El Arquitecto Peruano* journal —and claimed for— the need for new social housing, as well as public spaces and green areas in the city. Around 1945, he and his team started to work in the "Lima Housing Plan", which was published in June that same year as part of the new Government initiative.[5] The idea was to provide a new urban and social model that could tackle what the journal had previously identified as "the unavoidable duty of educating the popular masses and raising their current degrading standard of living".[6]

Addressing the housing deficit, government officials and architects at the National Housing Corporation (CNV) in coordination with the National Urban Planning Agency (ONPU) starting to work on projects for mass housing and large-scale green areas in Lima.[7] In this context, the Peruvian *Neighborhood Unit* became the main design and planning instrument for the renovation and expansion of the city. In doing this, housing projects provided a variety of housing typologies, traffic separation, open green areas, recreational and educational infrastructure, commercial spaces, and sports facilities, reinventing the concept of neighborhood unit in different social, cultural and economic contexts. In the first projects, such as UV3, "nature" —or the open landscape to be more specific— had a fundamental role in the design. Nature was the "host" and the "setting" that provided all attributes to the place and gave meaning to architecture. Nature produced through the landscape design the spatial qualities, whereas, in the last projects, such as PREVI-Lima, "nature" had a secondary role. Nature —or enclosed landscape, more specifically— was placed in-between buildings, representing nature, and deployed as an instrument of architecture and urban design to ensure good living conditions.

2. MASS HOUSING IN LIMA'S VALLEY: BUILDING UV3 AS A NEW EDEN

Lima Housing Plan lead by Fernando Belaunde in 1945 hybridized urbanization models such as British Garden City, German *Siedlung*, American Neighborhood Unit along with the pan-European *existenz-minimum* concept with the Peruvian traditional urbanization and socialization patterns such as *plazuelas*, pedestrian pathways and balconies animating the public spaces. The ideas for the Peruvian Neighborhood Unit were adopted, adapted and transformed into local conditions several times, being the UV3 its first materialization. As an urban and social ideal, this new model brought the community to the forefront to promote social development.

The ideal of a group of houses surrounded by large green areas, enjoying gardens in-between the buildings were present in the modern culture since the mid-1930s, promoted in the CIAM congress and the modern master's projects, which Le Corbusier summarized as "sun, air and greenery". The provision of greenery in parks and gardens was not only an element for entertainment, but also for 'medication' in the context of a polluted city center. As pronounced by Belaunde in a conference in 1945:

5. El Arquitecto Peruano, "El Plan de Vivienda del Gobierno Peruano" (Lima: El Arquitecto Peruano N.98, September 1945), n.p.

6. *"El ineludible deber de educar a las masas populares y elevar su degradante nivel de vida actual"*. Fernando Belaunde, "El barrio unidad. Instrumento de descentralización urbana," El Arquitecto Peruano no.83 (June 1944): n.p.

7. See, Sharif Kahatt, *Utopías Construidas. Las unidades vecinales de Lima* (Lima: Fondo Editorial PUCP, 2015): 99-115.

"The study of communities as a whole, where everyone has equal access to sunlight, fresh air, and parks, and where a harmonious balance is achieved between homes and the essential public services that support them, encompassing civic, educational, religious, commercial, and recreational aspects, is perhaps the most captivating topic of our time."[8]

A characteristic of urban "life" in this project is the fact that, in UV3 (as UV Callao, and others projects from those years), architects search for solutions to housing crises in "the nature", finding the place in the middle of the valley to achieve a new urban life, with green areas as the main support for a new society. The complex is placed in the middle of nature. The building-city-landscape reintegration was the result of the search for building and urban environment in the open landscape. As Lewis Mumford pointed out, Howard's idea of garden city, *"is not a suburb but the antithesis of a suburb: not a more rural retreat, but a more integrated foundation for an effective urban life"*.[9]

UV3 has more than 85% of open areas and its central green area characterizes the project as a "metropolitan park". The playgrounds, reflecting pool and other spaces placed in that area, reinforces that idea of offering a natural environment —a natural house—to the low-income families. The creation of a new large-scale community inhabiting housing blocks in a green and pastoral landscape in the middle of the Lima Valley as part of the modernization project is the most compelling idea for the first generation of modern architects.

UV3, as UV in Callao Port, were designed on agricultural land, which allowed them to take advantage of the existing conditions of the pre-Columbian water channels that irrigated the area (derived from the Rimac river), as much as the fertile soil of the plot to quickly grow trees, bushes and different species. The visual relation to the Rimac valley is key to understand the idea of "nature". The idea of the 'natural house' as mentioned by Norberg Shulz, was projected to offer the experience of being surrounded by the natural landscape achieving freedom, and enjoying fresh air and vegetation in the connection between interior and exterior spaces, not only in residential spaces (porches and balconies), but also in the community spaces located in the central area.

In the other hand, the concept of Neighborhood Unit has been permanently renovated, and has incarnated different urban forms, housing typologies, programs and activities, taking root in particular realities where it has gained strength among citizens. Therefore, the Neighborhood Unit must be understood as a conceptual "support" in housing and urbanization developments in which nature played different roles. Two decades after UV3 was built and many different housing projects were completed, PREVI Lima was planned as new solution for low-income families, with a different urban design strategy, in which, nature and landscape had a secondary role in the configuration of the neighborhood.

3. MASS HOUSING IN LIMA'S OUTSKIRTS: BUILDING PREVI LIMA AS A NEW BABYLON

PREVI Lima was envisioned as a way out of an overwhelmed reality of housing deficit and economic scarcity, following what Jose Luis Sert used to

8. *"El estudio de la comunidad como un todo, en la que se implante una efectiva igualdad en cuanto al beneficio del sol, del aire y de los parques, en la que se establezca el necesario equilibrio entre las casas y los servicios públicos que las complementan, en el orden cívico, educacional, religioso, comercial y recreativo, es quizá el más apasionante de los temas del momento."* Fernando Belaunde, "Reflexiones a los nuevos Arquitectos," El *Arquitecto Peruano*, no. 101 (December, 1945): n.p.

9. Lewis Mumford, "The Garden city idea and Modern Planning" in Ebenezer Howard, *Garden Cities of To-morrow* (Cambridge Mass: MIT Press, 1965), 35.

Figure 1. CNV, Fernando Belaunde Project coordinator, Unidad Vecinal, SAN Archive, 1949.

Figure 2. PREVI Office, Peter Land, Director, PRELI Lima, Lima, Perú, 1968-1975. SAN Archive, 1975.

claim to be "urban minded", meaning, finding solutions to urban problems within the city, instead of abandoning it.[10] More than two decades after the completion of the first Neighborhood Unit, the housing deficit in Lima had only worsened. Internal migrations to the capital city in search for new opportunities of social development became the common denominator for thousands of families. For that reason, squatter settlements (informal neighborhoods), became the most effective instrument of urbanization and the access key to housing options in the urban areas.

Since the early 1950s, an enormous population in Lima has been living in squatter settlements in the city outskirts known as "barriadas". These areas expanded as immigrants pushed their homes out into the desert in search for new empty areas. Between 1940 and 1972, Lima grew from nearly 660 000 to 3'420,000 inhabitants, by approximately 500%. Following the principles of the 'site-and-service' projects (included into the 1962 *Ley de barriadas*), new ideas emerged to construct urban encounters, using urban design elements to provoke urbanity. These strategies reveal the merger of two different responses that were manifested in cultural productions.

In this context, the strategy of low-cost, high-impact popular housing was resorted to "site-and-services" urbanizations, combined with "self-help construction" and complemented by "social organization". With this, CNV offices went from planning large works of housing towers, bars and blocks and commercial, educational, and recreational services for thousands of inhabitants, to "design" large plots for housing, and assigning spaces for

10. Jose Luis Sert, *Urban Design Conference*, Washington DC, 1953, JSL Archive, Special Collections Department, Harvard GSD.

"future services and community infrastructure", foreseeing in the organization the future collective construction of schools, markets, churches, parks, among other spaces for social development.

In PREVI Lima, the 'open-end' design approach was absorbed to integrate the popular knowledge from the existing (informal) city, as well as integrating traditional local spaces such as small squares, alamedas, and porches, in this high-density neighbourhood. The construction of a progressive single-family housing development, organized in small-scale clusters with lush gardens celebrating the collective spaces, was successfully achieved in PREVI Lima, and other similar projects such as Tupac Amaru and Los Proceres, was the response to the same idea of providing "small community" spaces animated with vegetation to foster social integration.

In this way, PREVI Lima achieved its goal of being an evolving neighborhood, recreating the natural scene throughout gardens, planters, and green spots in all small plazas was one of the great contributions. This network of instant urban oasis offering a "natural environment" is crucial in the character of the place. The inventiveness and biggest potential of the project was to *architecturalize* nature in these small spaces, bringing together the residents and turning the place into an inhabitable 'open-work'.

The participation of its residents to build progressively the collective urban form and its green spaces is crucial. It is in the juxtaposition of *artifice and nature*, that architecture played a key role of completing the urban space with natural areas ensuring quality of life. Most likely, this compenetrating relation established between architecture and the residents throughout the construction and self-help has produced and consolidate the idea of the "natural house" in its spaces, particularly through the freedom of every user to transform their houses.

4. CONCLUSION: THE ROLES OF NATURE IN ARCHITECTURE

The concept of a Neighborhood Unit can be defined as a set of residential buildings of different types, civic and commercial buildings organized around public spaces and articulated to generate an ideal citizen environment, that is, a development that provides basic activities and services such as commerce, education and entertainment within a pedestrian human scale place, which generates its own sense of urbanity. In the postwar period, experiments and constant reviews to achieve social development appropriate to material and economic limitations, the concept of Neighborhood Unity in Lima was consolidated as the social condenser of ideals that evolved throughout the time absorbing different goals, including the role of nature in the urban realm. As Iñaki Abalos has stated, the notion of *nature* is a cultural "construct" that "*undergoes changes and mutations in direct relation to the organization of the knowledge of different cultures*".[11] In this way, the neighborhood unit act as a framework to implement different ideals of modern urban life, which has allowed new models of urbanity be experimented.

During the mid-1940, UV3 was projected based on free-standing structures, surrounding a large open green space and surrounded by

11. Iñaki Ábalos, *Atlas pintoresco. Vol.1. El observatorio* (Barcelona: Editorial GG, 2004), 90.

thousands of trees (re)presenting an Eden-like environment for the low-income families in Lima. The former agricultural land was transformed into a colossal naturalized environment, that contributed to improve citizens' urban daily life. Later on, during the late-1960, PREVI Lima was conceived as a systematized network of flexible housing clusters and open spaces flourished by green areas throughout ensuring quality of life. In this arid part of the city, the main goal was to provide pathways, plazas and porches along with new green areas, planters and gardens, to provide shadow and fresh air to the places of social encounter.

All of these experiences have become part of the universal culture of architecture and urban projects in the international scene and offer to the present vivid testimonies of an array of ideas and ideals that were at stake in the design of single-family houses, collective housing and the urban spaces of the modern city. ■

MODERN HOUSING PRODUCTION ON THE AXIS OF INDUSTRY: THE EXPANDING BOUNDARIES OF ISTANBUL

YILDIZ SALMAN

ISTANBUL TECHNICAL UNIVERSITY

ABSTRACT

Modern housing's quest for contact with nature can also be observed in a series of labour houses in Istanbul. Industrialisation, which began later than in European cities, led to a sudden increase in the population of Istanbul, and the resulting housing issue emerged. Migrants built their own houses in the absence of any initiative to produce planned neighbourhoods, leading to many slums, particularly around the industrial areas. The risk of urban sprawl caused by housing problems made intervention necessary. European experience was utilised to shelter low-income labour. Since the existing legal framework prevented the construction of low-cost planned neighbourhoods for labour, the government made the necessary adjustments: Türkiye Emlak Kredi Bank, which financed the construction, was established, and a law authorising the operation of housing cooperatives came into effect. These cooperatives built numerous labour houses near industrial areas during the 1950s, starting with row houses and transitioning to block apartments by the 1960s. The study examined five neighbourhoods associated with industrial areas that had the most contact with nature. These neighbourhoods were local adaptations of German siedlung, and the research of construction processes contributed to the city's housing production history. Relevant industrial plants, most of which began production in the 19th century, including a textile mill, a bus garage, and a dockyard, were demolished as part of new development projects. A brewery and another textile mill were more fortunate and are still in use with valuable adaptive reuse projects. The labour houses associated with these plants are still in existence though they have not been extensively studied architecturally. However, Istanbul's rapid urbanisation and ongoing transformations put their existence at risk. The study aims to clarify the background of labour housing production, to contribute to their representation, and, most significantly, to investigate their potential for the future.

1. INTRODUCTION

Turkey restructured and emphasised industrial production in the first quarter of the 20th century. As bureaucrats moved to Ankara, the new capital, the way was paved for the industry in Istanbul. Some 19th-century industrial buildings were reused with annexes, while new plants were also built. Post-war economic problems affected Turkey, although it did not participate in WWII. People having financial difficulties in rural Anatolia began to migrate to cities, and this internal migration provided the labour force needed for industrial growth. However, housing the growing population became an essential problem for Istanbul. Labour housing cooperatives played a role in addressing the housing shortage. In addition to rationalisation and standardisation, some of these products were in contact with nature and were able to respond to the demands of modern housing.

2. THE HOUSING PROBLEM AND BEYOND

With the rise of industry in Istanbul, immigrants began to dominate areas formerly inhabited by high-income groups for centuries. The economic problems following WWII and the relocation of high-income groups prevented the planned housing construction and led to the lack of maintenance of existing residential stock. As Istanbul's population surged, housing solutions fell short closer to the middle of the century. The city's new residents sought to address their housing needs independently, as there were no initiatives to deal with the housing problem.[1] This led to the emergence of slums especially in the vicinity of industrial complexes. Skidmore et al. identified severe hygiene problems in their studies about these slums, and they warned of the risk of health problems for future generations.[2] Recognizing the dual threats of urban sprawl and public health crises in Istanbul, efforts to tackle the housing problem began.

The first steps to address the housing issue in Turkey were taken immediately after WWII. However, following preliminary studies and unsuccessful experiments, housing production only began in the 1950s. First, the government established the Türkiye Emlak Kredi Bank in 1946, modelled on the French Crédit Foncier system.[3] By the early 1950s, the bank had built the first planned housing complex in Istanbul, Levent and Koşuyolu. These neighbourhoods, in the British garden-city typology, were built in phases.[4-5] Given the limited municipal involvement, the Bank built not only the housing units but also the infrastructure, roads, and streets. Consequently, house prices rose, making these areas geared more towards the upper middle class, despite the growing housing needs of low-income workers. Thus, the Bank's housing projects, designed with higher quality and luxury than necessary were criticised[6] by various circles. Nevertheless, the Bank's constructions provided valuable experience in planned housing production.

3. PRODUCTION OF LABOUR HOUSING COOPERATIVES

Law No.6188, enacted in 1953, allowed for housing cooperatives to build homes on land with a master plan provided by the municipality and financial support from the Bank. Construction surged, and the well-known architect Seyfi Arkan was commissioned to manage the master plan studies.[7] Arkan and

municipal architects designed and prepared many master plans.[8] Labour housing cooperatives constructed two-storey single-family houses like the Bank. However, they preferred the more affordable row houses instead of detached units. Although production continued until the mid-1960s, a new legal arrangement established by the Condominium Law, enacted in 1965, provided the legal basis for multi-storey buildings,[9] leading cooperatives to shift towards apartment blocks.

When industrialisation began in Istanbul, the outskirts of the historical settlements were chosen for industrial activity in the 19th century. The first plants were established west of the Historical Peninsula, north of Pera, around the Golden Horn, and on the far shores of the Bosphorus. In the early 20th century, production persisted in these facilities under various corporate identities.[10] Similarly, the new plants were located on the city's periphery at the time. Following proper legal arrangements, labour housing cooperatives planned and constructed modern neighbourhoods near industrial areas. These neighbourhoods were designed within the framework of longer-term urban planning in mind and made significant contributions to the development of their environment. Infrastructure systems were extended to these environments, and public transportation services made them more accessible. Although the history of plants dates back to the 19th century, Istanbul's industrial areas became part of the city only in the 1950s when planned labour housing was implemented. Continued domestic migration from this date led to rapid urbanisation, and the industrial areas of the mid-century became urban centres over time.

3.1. LABOUR HOUSES AS A TRANSPOSED TYPOLOGY

The housing problems resulting from industrialisation were not unique to Istanbul. A similar case occurred in almost all European cities following the Industrial Revolution. However, the tenement typology developed to solve this problem often failed to provide enough air and sunlight,[11] and soon proved impractical. At the beginning of the 20th century, the issue of labour houses in healthy environments, which was on the agenda of industrial cities, was also a widespread discussion in architectural circles. It is essential to examine the emergence of the modern housing concept before discussing the housing problem. Frank Lloyd Wright designed a wide range of houses in the United States around the same time. These were detached single-family houses built in suburban or rural settlements.[12] The new models differed in design from all previous samples and revolutionised housing design. Norberg-Schulz analysed Frank Lloyd Wright's production as a new kind of informal living with natural materials, simple, straightforward artefacts, and, if possible, contact with a natural environment.[13] Wright's approach influenced the ongoing struggle to address housing problems, which intensified in Europe after WWI. The Neues Bauen movement, which emerged in Germany and was characterised by the standardisation and rationalisation principles[14] of Modern Architecture, set the standards for the period with its productions in Berlin and Frankfurt. Although these new siedlung typologies could not use natural materials like Wright, they never compromised on being simple, plain, and in contact with nature.

Akcan states that German siedlung ideals were adapted to produce planned neighbourhoods in Turkey.[15] Therefore, neighbourhoods built by labour housing

cooperatives can be deemed local siedlung models. Due to climate conditions, certain changes in building design and construction were inevitable. In addition, due to the topography, it was impossible to see the straight lines of the vista and the perfect alignment of the German siedlung in Istanbul. Contact with nature was a sine qua non-criterion in discussions on the production of planned neighbourhoods in Turkey. The European experience could not be ignored in this process. In one of the early discourses, Vietti Violi stated that the labourers in newly industrialised Turkey used to be farmers, accustomed to living outdoors and now spent all day long inside factories. To facilitate their swift transition to urban life, it was crucial that they spend their recreation time in houses that were suitable for their old lives, with their gardens.[16] On the other hand, Oelsner declared that in the siedlung settlements, the largest room in the house was the garden, which was the element that enriched and gave meaning to the modest housing unit.[17] Expert opinions on contact in nature guided decision-makers in housing production. In 1951, the Istanbul Municipality included the following article in the regulations it prepared for the social housing groups: Residents are responsible for maintaining and nurturing the trees to be planted in front of houses and gardens. In case of destruction, they must plant a new tree in the same place. It can be assumed that labour housing cooperatives were also produced in accordance with these regulations and that architectural designers considered contact with nature. In the meantime, in 1942, the National Economic Institute promoted the idea modern urban residents connecting with nature with the slogan: "The citizen grows fruit and vegetables, both to decorate and to feed." Ihap Hulusi, a prominent illustrator of the period, designed a poster depicting this slogan with people gardening in front of housing units **(Fig. 1)**.

3.2. ISTANBUL'S LABOUR HOUSES IN CONTACT WITH NATURE

Labour housing cooperatives began construction after the necessary arrangements were made for planned neighbourhoods. Housing units required gardens to be in contact with nature. However, some neighbourhoods were built in the dense pattern of the old town, while others were built within industrial plants and could not touch nature. Within the scope of the study, the labour houses analysed were built where contact with nature is most evident **(Fig. 2)**.

In 1937, Sümerbank assumed the management of Istanbul's important textile mill, Feshane. Although the Feshane labourers' housing cooperative was

established in 1950, it could not produce until legal regulations were enacted. The cooperative was reactivated in 1954 and bought land. In the same year, the master plan for the land was designed by architect Güngör Kaftancı. Construction of 200 units of housing continued until the late 1950s.

TEKEL was the sole producer and distributor of all alcohol and tobacco products in Turkey. Istanbul's first brewery, Bomonti, built in 1902 in the north of Pera, was taken over by TEKEL 1934. The brewery labourers' housing cooperative was founded in 1952. Istanbul Municipality provided land for the cooperative, and Arkan's team prepared the master plan. The neighbourhood, comprising 123 housing units, commenced construction in 1955 and was completed in 1957.

Sisli Bus Garage was built in 1949 with a modern parking lot and repair shop. The housing cooperative of bus garage labourers was established in 1956. The cooperative purchased land and architect Ergun Evrenol completed the master plan for the neighbourhood in 1958. The construction of Etiler Labour Houses, with 100 units, was completed in the early 1960s.

Istinye, situated on the far shores of the Bosphorus, has a long history of repair yards since the mid-19th century. An extensive dockyard was established here in 1912. The dockyard became state property in 1928. The Istinye Dockyard labourers' housing cooperative was founded in 1952. Arkan's team designed a master plan for a plot of land belonging to the municipality. However, that project was never built. A newly approved master plan in 1965 initiated the construction process of the Istinye labour houses. The neighbourhood, completed in 1967, had 136 units.

All of the case housing groups were constructed as two-storey row houses. In Bakırköy, Mecidiyeköy, and Etiler, each unit was inhabited by a family, while in Eyüp and Istinye, the ground and first floors were occupied by different families. All cases were designed for labour, offering optimal comfort and minimal construction costs, resulting in a simple and straightforward architectural style. The contact of the housing units with nature was possible at different points. In all cases, the units were designed a few meters back from the street, with a small front garden in this area. The front gardens were modest green spaces that provided the transition of the units into the public sphere, buffering the street activity from the tranquillity of the house. Low clotures defined the boundaries with the street and the adjacent front garden. The actual contact with nature was only possible in the backyard. Backyards were quite large and were family-only spaces with no public access. Instead of front gardens where seasonal flowers were grown to adorn the house with the beauty of nature, the backyard served as both a recreation area for the family and a fruit and vegetable garden. The boundary elements of the backyard were not clotures or fences but landscape elements such as a tree and natural stones placed in the corners. When shared with a friendly neighbour, the backyards had no boundary. The backyards, adjacent to each other between two parallel streets, looked like urban-scale green areas in Bakırköy, Eyüp, and Mecidiyeköy labour houses. Since Etiler and Istinye labour houses were on sloping land, only a unit and its backyard could be terraced. The backyards provided an opportunity to wile away the time while maintaining contact with nature. The backyards allowed residents

to observe seasonal changes and plant growth, and it was claimed they provided basic nutrients like vegetables and eggs.[18] Areas where neighbours could spend time together were just as crucial as the gardens used by families. In Bakırköy and Mecidiyeköy, parks with playgrounds and recreational areas were planned within the neighbourhoods to provide contact with nature. The parks planned at the end of the housing rows allowed for contact with nature and isolated the units from the noise and pollution of the main street in Eyüp. The sloping land of Etiler and Istinye prevented the planning of an additional nature contact area.

4. CONCLUSION

In the 1980s, global economic tendencies were bolstered by national-level privatisation. Many state-owned industrial plants were sold or privatised, and production was halted. This led to the transformation of labour houses. In the 1990s, labourers from these retired plants moved to settlements near their new workplaces. These neighbourhoods were situated on the outskirts of Istanbul but were transformed into centres over time with the city's rapid urbanisation. After the abandonment of labour, higher-income people and small businesses preferred the neighbourhoods. The new users did not hesitate to intervene in the housing units according to their needs, and over time, the integrity of the neighbourhoods suffered. Furthermore, the areas where houses were in contact with nature also had their share. Front gardens were paved for parking lots, while backyards were used for the construction of new places to meet additional needs. However, these areas have the potential as urban green spaces in terms of resilience, sustainability, and wholefood and should be preserved.

The housing problem in industrial cities is a global phenomenon. In contrast to European cities, Istanbul encountered this at a later stage. The labour housing in Istanbul plays a significant role in modern architecture's history. It is essential for urban history due to its pioneering role in expanding boundaries and as the indirect place of 20th-century industrial production. In this context, documenting these structures is critical in developing proposals to sustain their existence. The cases within the scope of the study are relatively fortunate in terms of maintaining their authenticity and integrity. However, many similar 20th-century housing examples, essential for illustrating the industry-housing relationship, have been demolished or transformed due to neo-liberal policies. There is an urgent need for a new 20th-century narrative and conservation perspective, considering these housing cases' architectural and social heritage. ■

INSTITUTO DE HISTORIA
FACULTAD DE ARQUITECTURA, DISEÑO Y URBANISMO
UNIVERSIDAD DE LA REPÚBLICA

ABSTRACT.

Exploring the history of local social housing, works and events emerge from the period spanning the late 1960s to the mid-1970s. During that time, regulatory frameworks were established, and key, disciplinarily interesting, housing complexes were constructed. Participants in this process belonged to different generations, professions, and political backgrounds. Beyond an evident interest in housing, they did not seem to share other common motivations. However, many shared an often overlooked commonality: involvement in the local Catholic cadre.

The study of Catholic social space reveals a constant appreciation for rurality that stood in contrast to the city, coinciding with an architectural movement that questioned the values of large urban centres. Catholics envisioned a utopia that sought the re-enchantment of the modern world through the restoration of family life and community, the recovery of roots and stable relationships with the land, creative work, and artisanal techniques. The strategy involved two operations: civilising the countryside and ruralising the city, building houses in villages and garden suburbs.

Based on these premises, this paper examines and interprets the first housing complexes built under the cooperative system in the suburbs of Montevideo. It contends that their location, features, forms of association, and compositional resources stemmed from the ideas and initiatives of Catholic agents, who were key in recovering values and countering the effects of secularisation. The research relies on primary sources and evidence arising from an ongoing doctoral thesis at the doctoral program at the Facultad de Arquitectura, Planeamiento y Diseño de la Universidad Nacional de Rosario.

Between 1969 and 1970, Montevideo saw the construction of the first housing complexes under the cooperative system, under the responsibility of the Centro Cooperativista Uruguayo (CCU) for technical assistance.[1] COVIMT 1, 2, and 3 were located in the city's northern outskirts. These efforts extended the early experience in rural towns towards the interior of the country, where self-management, common ownership, mutual aid, tested building types, appropriate technologies for unskilled labour, and assorted forms of unit association had been experimented with.

For the design of the Montevideo complexes, Mario Spallanzani adopted two compositional structures used in inner cities. Ruling out the block logic that organised the COSVAM cooperative built in Salto, he adopted the centralised organisation, reminiscent of that used in the Isla Mala cooperative in Florida, and the meandering line, defining the Éxodo de Artigas complex in Fray Bentos.[2]

The houses displayed exposed brick walls with staggered joint masonry, and sloping roofs with brick tiles, fibre cement sheets, and supported by concrete beams. Spallanzani designed two types of units. The single-level typology is quite similar to that used in the complexes in Salto and Fray Bentos. Additionally, for these complexes, he designed two-storey units. By incorporating duplex houses, he managed to reduce the frontage dimension to just five linear metres. This approach maximised space for gardens in the front area of the houses and communal garden areas.

1. COMPOSITIONAL ELEMENTS OF THE COVIMT 1, 2, 3

COVIMT 1 Cooperative was the first mutual aid and user-regime project to be built in Montevideo. Architect Miguel Cecilio led the group of participants, collaborating with social worker Daisy Solari and Spallanzani on the design. The development includes twenty two-bedroom houses and ten three-bedroom houses, all of which are duplexes, with one exception. They were arranged in two rows of fifteen units each, facing each other, with gardens at the front and vegetable gardens in the back. To avoid symmetry, Spallanzani employed two operations. He staggered the rows along the longitudinal axis slightly, taking a dimension approximately equal to half the width of a dwelling. This resulted in a slight delay in the western row marking the entry to the complex, accentuated by the short distance between the first two houses located on the street **(Fig. 1)**.

Towards the south, he successively withdrew the units, then repositioned them from the midpoint of the site. The setback of the houses exposed the blind party walls, accentuating the texture of the exposed brickwork. Additionally, it avoided monotonous front facades by creating visual excitement through volumetric variations offered by the typology in the elevations.

Those corresponding to the houses located in the centre of the composition are almost half the size of those at the ends. The sacrifice of individual lots was compensated by expanding the communal garden area. By significantly widening the interior area, a private communal space for the residents was created, enclosed by the site's boundaries.

2. Mary Méndez, "Catolicismo y ruralidad en los sesenta. La civilización del campo y el inicio del cooperativismo de vivienda," in *Casas Comunes. Arquitectura para la vivienda social en Uruguay*, ed. Mary Méndez, Santiago Medero, Martin Cajade and Pablo Canén (Montevideo: Fadu, Udelar, 2024), 318-330.

The undeveloped area of this complex is very large, encompassing 83% of the property. A collective unbuilt area, making up 38% of the total land, is designated for gardens and pedestrian paths. Private unbuilt spaces, including front gardens and rear orchards, account for 34%, while vehicle paths occupy the remaining 11%.

In designing the COVIMT 2 cooperative complex, architect Cecilio collaborated once again with Spallanzani. The development consists of 43 duplex units: 24 of which have two bedrooms, fifteen have three, and four others have four bedrooms. The land is rectangular, covering slightly more than 1.5 hectares. The houses were arranged in three rows and placed along a winding road. Some of the resources already tested in the previous complexes were used there, such as the staggered longitudinal rows to mark the access, setbacks, and also the display of blind party walls. However, a greater regularity is observed in the composition of the facades, achieved by using groups of two, three, four, or five units as the basic compositional unit.

In the overall organisation of the layout, a decision was made that inverted the compositional logic of COVIMT 1. Here, the complex opens towards the ends, narrowing towards the centre of the site, creating a strong sense of very efficient introversion. This effect is enhanced by the turn established by the street and partially hiding the complex. A square that results from separating the two eastern rows provides continuity to the collective use space. In this design, the unbuilt area is also very substantial, occupying 81% of the property. It is distributed into a collective-use unbuilt area that occupies 42% of the total land designated for tree-lined plazas. The private unbuilt area hosts front gardens and rear orchards, occupying 39% of the total, with the remaining 11% taken up by a vehicle path **(Fig.2)**.

The COVIMT 3 cooperative, made up of Aurora textile factory workers, began meeting in 1968. The 44 duplex houses were arranged in four rows facing each other, overlooking a longitudinal park crossed by pedestrian paths. In the initial design, the complex opened towards the busier east street, while the quieter west side had no buildings. The funnel-like shape allowed for a plaza facing the main street and drew people towards the back, creating a gradient of intimacy.

The finally constructed project has some significant variations from the initial proposal. The most notable change was the disappearance of the funnel shape, replaced by a symmetrically-based organisation. Although altered by the setbacks of the house groups in the rows, the effect is one of greater overall regularity. The image of houses aligned along a traditional street is accentuated by the interior vehicular path, which was built instead of the originally planned garden. The vehicular street reduced the area designated for squares and collective gardens, resulting in an increase in impermeable surfaces and a lack of trees.

However, a substantial total unbuilt area was maintained, at 80% of the property. The unbuilt area for collective use occupies only 26% of the total land, increasing the private unbuilt area with front gardens and rear orchards, which occupy 46% of the total. The vehicular path takes up the remaining 8% **(Fig.3)**.

2. PERSISTENCE AND UPDATING OF THE TRADITION OF THE GARDEN SUBURB

According to Spallanzani, the two-storey houses he designed for these complexes were inspired by those built in the new satellite cities of the Greater London Plan. In an interview conducted in 2015, the architect indicated that his work at the CCU had been influenced by the architecture being built there. He pointed out that the typologies of the Montevideo complexes were particularly related to those used in the city of Harlow.[3]

The master plan design of Harlow was projected for 60,000 inhabitants and was led by urban planner Frederick Gibberd. It was the first to be approved in 1947. Located in the northern periphery of London, it followed the design guidelines of Raymond Unwin's garden suburbs. The proposal relied on the installation of industrial areas, the separation between vehicular and pedestrian traffic, and the construction of a civic centre. The houses were grouped into neighbourhoods where families could establish community relationships. Thirteen neighbourhoods were considered for a population between 3,500 and 6,000 people each. Each neighbourhood, unique in its physical organisation, formed a community with a primary school, shops, and buildings for common use. The operation included the incorporation of parks, greenery, and trees alongside areas of agricultural land.

For the housing, Gibberd defined a two-storey typology, with gardens at the front and orchards at the back, avoiding separative elements defining the plots. He chose dark brick walls and pitched roofs covered with tiles. Most were arranged in regular rows, some stood alone, and provisions were made for grouping in towers. Gibberd pointed out the advantages of duplex houses arranged in rows, as they were more economical, but above all, because they allowed for the creation of urban environments, he considered beautiful.[4]

The villages of the Greenbelt were known to Uruguayan architects through Gibberd's books and the English magazine *Architectural Review*, and they were highly regarded. The composition of the complexes designed by Spallanzani expresses a clear relationship with these urban designs. As with the London New Towns, the first suburban cooperative complexes in Montevideo updated the tradition of the garden suburb in the local context. In the 1960s, lessons learned in the first half of the 20th century were recovered, and the main references were reviewed, including Werner Heggeman, Camillo Sitte, Lewis Mumford, Raymond Unwin, Patrick Abercrombie, and Thomas Sharp.

However, it is important to note that the complexes designed by the CCU had other motivations. While the network of satellite neighbourhoods in London aimed to control the growth and sprawl of the urban area, eliminating the proliferation of uncharacterised peripheries, Montevideo's complexes chose to settle on the urban edges, establishing a population in peripheral areas and fostering a suburban culture.

Due to their small size and lack of inclusion in a comprehensive urbanisation operation, each cooperative housing complex constitutes a fragment, disconnected from its surroundings. They consist of individual, isolated solutions marked by strong introversion. Each one presents the image of a small, closed, and

disciplined village community, comprised of families, which starkly contrasts with the bland areas where they are located. They articulate a positive moral appraisal of rural values, communal gardens, home, family, and community.

3. CATHOLIC MATRIX EVIDENCE

The suburbs were seen as a potential blend of rural charm and urban sophistication. Cooperative complexes aimed to bring a rural touch to urban spaces, limiting crowding, eschewing high density, and regulating upward growth. Discussions on city life values from a disciplinary standpoint aligned with principles rooted in the Catholic faith.

The research and work with the primary sources on which this paper is based enable us to affirm that it was the actions carried out within the Catholic social space and the ideas upheld by Catholics that made it possible to materialise these works. Below, evidence of this is presented, using a genealogical strategy that explores the formative years, beginning with an initial observation.

3.1. EVIDENCE ONE.

The chapter that established the legal framework for housing production under the cooperative system of the 1968 Housing Law was drafted by architects Juan Pablo Terra and Cecilio, incorporating the experiences of Irureta, Spallanzani, and Solari. Architect Horacio Terra Arocena was then president of the Instituto Nacional de Viviendas Económicas. Almost all of them were part of the local Catholic cadre. The two Terras, a father-and-son duo active in politics, represented political parties linked to the Church in the Uruguayan parliament. Juan Pablo advocated for the creation of two institutions inspired by the ideas of Louis-Joseph Lebret. Irureta and Solari had longstanding leadership roles in lay youth organisations. The CCU was created by Bishop Luis Baccino, along with a group of Catholic militants trained in cooperativism at the Catholic University of Leuven. Irureta and Solari were two of the technicians who created the division responsible for housing in that institute.

3.2. EVIDENCE TWO.

Beginning in the 1940s, a distinctive philosophy regarding housing started to take shape within the Catholic social context. Between 1935 and 1957, the *Tribuna Católica* magazine was the authorised interpreter and disseminator of Catholicism in Uruguay. Terra Arocena was its director between 1941 and 1944, and again from 1949 to 1957. A review of its pages confirms the persistence of the spiritualism of Henri Bergson, the notion of the Common Good, and the promotion of collective forms of property derived from Integral Humanism by Jacques Maritain, the need for the development of people's spiritual values, and the community civilisation promoted by Emmanuel Mounier. The magazine disseminated Lebret's ideas through institutions created under the imprint of Human Economy.

3.3. EVIDENCE THREE.

Among lay militants and local catholic hierarchies, there was a persistent admiration of rural life and a strong aversion to urban life. The tension between

the countryside and city and the interest placed in rural matters emerge from *Tribuna Católica* and the book *Detrás de la ciudad. Ensayo de síntesis de los olvidados problemas campesinos*.[5] Throughout the book, elements are presented that articulate the proposal to modify the situation: the creation of villages composed of farming families trained in agricultural schools, living in hygienic shacks. The promotion of productive villages not only aimed to alleviate rural poverty but also to encourage the urban population to return to the countryside, which would result in the integration of agrarian spirit into national life.[6]

3.4. EVIDENCE FOUR.

The Law of Populated Centres, an initiative of Terra Arocena, was the first legal instrument to bring these proposals to life. The National Foundation Friends of the Rural Child united Catholic agents and urban planning technicians from the Institute of Urbanism of the Faculty of Architecture with the mission of creating orchard villages, incorporating cooperative production. They believed that they would transform the inhabitants of shantytowns into happy farmers, exerting a civilising influence on the country, and humanising rural territories through a new exemplary lifestyle.

3.5. EVIDENCE FIVE.

In the orchard village of Polanco del Yí, the construction of houses through mutual aid was experimented with for the first time in Uruguay. It was believed that it would not only foster communal living but also build the necessary collective spirit. The village represented the initial application of architect Carlos Gómez Gavazzo's ideas in creating a territorial settlement model, which culminated in his theory of Rural Planning in Uruguay.[7] The collaboration with Catholic agents also influenced Mauricio Cravotto in defining his theory of the "Happy Village" and in recognising the need for a "village doctrine" to initiate a new housing policy.[8] Mutual aid was applied for economic reasons, but the positive acknowledgement of collective construction was accompanied by other motivations. The joint effort not only aimed to produce architectural works but also to build community, foster group development, involve people in the finished product and collaborate in subsequent actions. Thus, by building the house, they shaped individuals, the family, and the community.

3.6. EVIDENCE SIX.

They used local materials and artisanal construction techniques conducive to mutual aid. They associated the concept of useful and joyful work with this particular form of collective production, contrasting it with alienated labour. With this, they picked up on a tradition that dated back to the thinking of John Ruskin and William Morris, critics of factory production and industrialisation.

3.7. EVIDENCE SEVEN.

The location of housing complexes on the urban peripheries implied a continuity with rural life, valued in the encyclicals and pastoral letters of John XXIII and Paul VI.[9]

3.8. EVIDENCE EIGHT.

The significance of the nostalgia for Paradise in Eden within the matrix of Catholicism and the possibility of its recovery through architecture.

4. CONCLUSIONS

Catholic agents played a crucial role in promoting and carrying out low-income housing projects in Uruguay. Their influence extended from the creation of institutions to the promotion of laws and the shaping of public opinion. Following Michael Löwy in his studies on Catholics in Latin America, it is possible to consider that, starting from the diagnosis of modernity as rupture, Catholics committed to a common utopia: restoring family life and community, reclaiming roots and stable relationships with the land and nature, fostering creative work, craftsmanship, and joyful labour. They promoted housing cooperatives as privileged instruments to recover values and resist the disillusionment of secularisation of the modern world.

The homes built through mutual aid demonstrate the success of their intentions. The system of collective tenure, a system contrary to private property, aligns with the Thomistic Common Good. The first cooperative housing complexes took the form of houses, formally defined yet clustered together, a physical correlate of family life in neighbourhood relationships. Their modest size fostered close-knit relationships among neighbours. The location in peripheral areas, and the presence of orchards and gardens, derive from a moral interpretation of natural environments. Life could be purified and cleansed by caring for flowers, cultivating orchards, and creating communal gardens to provide a framework for enriching community experiences. ■

BIOGRAPHY

Mary Méndez (Montevideo, 1969). Graduated as an architect (Faculty of Architecture, Udelar, 1997), and holds a master's degree in History of Architecture (Universidad Torcuato Di Tella, 2013). She is currently a doctoral candidate at FAPyD, Universidad de Rosario and professor in the Department of History of Architecture at the Institute of History (Facultad de Arquitectura, Diseño y Urbanismo, Universidad de la República) where she holds a full-time position. She serves as Director of the Institute of History, and is responsible for research, and teaches courses on the History of Architecture in Uruguay and Thought and Design in Uruguay. Méndez is also a member of the National Researchers System (ANNI, SNI), and author of several books and articles in national and international journals.

DEVICES FOR THE PERCEPTION OF NATURE. RICHARD NEUTRA'S SUBURBAN SINGLE-FAMILY HOUSES

MATTHIAS BRUNNER
HAUTE ÉCOLE D'INGÉNIERIE ET D'ARCHITECTURE FRIBOURG

#12

ABSTRACT

The issue that Richard Neutra was most concerned with was the relationship between humans, nature, and architecture. Since humans have evolved in nature, he believed that their physical and mental health depends on contact with nature. Consequently, he focused on the question of how external nature (the environment) affects the biological nature of man, and what this means for the design of the human habitat.

This paper explores how Neutra understood the relationship of architecture, humans, and nature. It looks at the features of nature that, in his view, characterize good suburban building sites. It analyzes how he planned suburban homes and their surroundings to provide residents with closeness to nature, spaciousness, and privacy. And it asks how the relationship of the building to nature changed when he began designing courtyard houses on smaller lots. To this end, it uses mainly primary sources and often refers to the case studies of the Kaufmann Desert House (1946–47) and the VDL Research House (1932–33, 1939–40, 1963–65).

The results indicate that for Neutra, nature is not something untouchable, but something that can be improved, staged, and even simulated without losing its positive effects. In suburban environments, he felt that such manipulations of nature were necessary to do justice to human nature. Yet he did not believe that it is possible to breathe life into architecture so that it becomes nature itself. It remains an artifact that must subordinate to nature by becoming a device for the perception of nature.

1. INTRODUCTION

The issue that interested Richard Neutra most throughout his life was how humans, nature, and architecture interact. Accordingly, he read numerous books on subjects related to the nature of the environment and the nature of man. Concerning the environment, he was particularly interested in evolution, ecology, zoology, and ethology; regarding the nature of man, he was most curious about philosophy, anthropology, ethnology, medicine, visual perception, and nearly all branches of psychology. His writings reflect his readings.[1] In practice, his thinking about nature had an impact on the urban layout, the evaluation of the site, the orientation and placement of the building, the landscaping, the façade treatment, the selection of materials and colors, and the climate control.

Although, as with nearly all architects, Neutra's theories are not as important as his built work, it is inevitable to study them carefully to understand his work in depth. Existing research has struggled with this task. Some have not given much space to his theories, concentrating mainly on stylistic and biographical issues.[2] Others have stayed so close to his texts that they have added little to what he has already said.[3] Still others have shown that his techniques for relating to nature are more deeply embedded in contemporary debate and practice than is evident from his writings, but have not done full justice to the specific character of his approach.[4]

2. UNDERSTANDING NATURE

Neutra understands nature not as something opposed to humans, but as something to which humans, as living beings, belong. Since humans evolved in nature, he believes that they are only adapted to the types of sensory stimuli that nature provides. When humans are exposed to stimuli to which they are not adapted because they are new or beyond their perceptual capacity, their physical and mental health is threatened. Such stimuli originate primarily from man-made, chaotic environments such as unplanned, noisy urban places. Colored neon lights, overhead power and telephone lines, and the arrhythmic flow of road traffic are examples.[5] All human interventions in the environment—from roads to cities to single-family houses—must therefore be designed to meet human biological needs. Identifying these needs and developing appropriate designs is a practical problem that is accessible to rational thought and has to be addressed with the help of all the sciences. Designs that fulfill this requirement are what Neutra calls biorealistic.[6] When it comes to architecture, their most important characteristic is their openness to the outdoors—to nature.

In keeping with his belief that architecture should be open to the outdoors, Frank Lloyd Wright's interweaving of interior and exterior spaces and his practice of engaging with the peculiarities of the landscape and the place always met with Neutra's full approval ever since he first studied the Wasmuth portfolio long before immigrating to the United States in 1923.[7] By contrast, he considered perfectly regular buildings inappropriate because of their inability to respond to the heterogeneous conditions of

6. Neutra used this term for the first time in Richard Neutra, "An Architect Worries About Organic Unity," 1953, Richard and Dion Neutra Papers (collection no. 1179). Los Angeles: Charles E. Young Research Library, University of California (hereafter cited as UCLA), box 161, f. 9.

the environment—the view, the wind, the sun. For example, he criticized Ludwig Mies van der Rohe for designing the façades of projects such as the Lake Shore Drive Apartments to be identical on all sides, placing formal purity and regularity above nature.[8]

Frank Lloyd Wright's request to design buildings that grow and take root made no sense to Neutra. In his view, this idea inevitably leads to a objectionable imitation of external nature. Instead, architecture should openly acknowledge that it is an artifact assembled by human hands.[9] To Wright, Neutra's argument was irrelevant because his Neo-Platonic view was that if he succeeded in designing a building according to the basic principles of nature, it became a manifestation of nature.[10] Neutra was also critical of the equally idealistic concept of Le Corbusier's Modulor. In his view, the Modulor mistakes a purely human and obsolete invention, the golden section, for a principle of nature.[11]

Yet Neutra did not want his buildings to appear as artificial as possible. He always considered the use of natural materials, such as wood or natural stone, permissible, and, beginning in the 1940s, highly recommended.[12] Similarly, although Neutra rejected the imitation of nature itself, in many cases he welcomed the simulation of nature's effects and the enhancement of nature. For example, he wanted to introduce dynamic artificial lighting that emulated the constantly changing color and brightness of daylight by means of dimmers.[13]

3. SELECTING THE SITE

In Neutra's eyes, large lots in the midst of a pristine landscape offered the best conditions for designing a house with a good relationship to nature. However, he felt that the suburbs, where most of his houses are located, often provided satisfactory conditions as well.

Of the qualities that characterize a good site, a good view, i.e. a view of an element of nature, was most important to him. Preferably this element was as far away as mountains, dunes, or lakes, because he believed that the eyes only relax when they accommodate to the distance.[14] Nevertheless, he also appreciated views of closer elements of nature, such as trees or gardens.

Neutra then argued for land with naturally formed relief, including hollows and streams. Consequently, he rejected the practice of "land developers and subdividers [...] who [...] wade through the bush and over the hills, cut the trees, excavate the good earth, bulldoze and bully the landscape, victimize it to the rectangularity of a gridiron [...] to get so and so many fifty-foot lots on the market."[15] In projects on large, ungraded lots such as the Tremaine House (1946–48), Neutra almost always succeeded in preserving much of the relief and carefully fitting the house into it, roughly following the movements of the relief. Accordingly, he criticized Le Corbusier's buildings on pilotis for ignoring the natural slope of the terrain.[16]

In addition, Neutra preferred sites with preserved vegetation, especially trees. At the Eurich House (1939), he used the huge old oak trees he had found on the property to frame and shade the building.

In his writings, Neutra also recommended considering several non-visual parameters such as climate, wind, sunlight, sounds, and odors when choosing a lot. In practice, however, apart from intrusive noise, these rarely played an important role, as it was more than difficult enough to find an affordable building site with a good view, a naturally formed relief and an old stock of trees.

Neutra was rarely able to influence the selection of the site, as his clients typically had just purchased or were in the process of purchasing a lot when they contacted him. Whenever possible, he visited the lots in person. As a rule, he had many photographs taken, for his memory and for his staff, who usually did not inspect the more remote properties. He also had contour maps drawn, with curves spaced one foot apart, showing prominent rock outcroppings and important plants, especially trees, with size and species.[17]

4. ORCHESTRATING SPACE

To connect the inhabitants with nature, Neutra opened up the building by removing walls and blurred the boundary between indoors and outdoors by extending architectural elements into the garden and integrating elements of nature into the interior. In this way, he interlocked the two areas and created a zone that mediated between the architectural artifact and the conceptually untouched nature.

The Kaufmann Desert House (1947), for example, is surrounded by a zone in which architectural elements that extend beyond the house, such as floors, walls, and roof overhangs, intermingle with elements of geometric ground design, such as the plateau around the swimming pool, and with geometric plantings, such as the lawn. This zone flows seamlessly into an outer, more natural area characterized by a lawn with scattered boulders, often combined with perennials or desert plants **(Fig. 1)**.

For spectators from within, Neutra orchestrated the view in a manner akin to landscape painting and stage design by combining the best distant views with scenically staggered horticultural and architectural screens. Thus, he created a "little visual empire"[18] that provoked a "feeling of spaciousness."[19] In most cases, the observers' backs were protected by a closed wall. This made them feel safer, Neutra believed, because it freed them from having to monitor the rear space for possible attackers with their generally forward-facing eyes.[20] In suburban areas, the screens and the closed back walls were given the second task of visually blocking out unnatural disturbances such as neighboring buildings and streets outside the property lines **(Fig. 2)**.

The prospects offered to passersby were not equally important to Neutra. Rather, he was primarily concerned with blocking certain views of them in order to ensure the privacy of the house. To this end, he again used the screens, giving them a third function. As a result, the streetscape is rather accidental and not always attractive.

5. NATURE IN DENSE ENVIONMENTS

As early as the 1920s, Neutra was averse to both living in the city's sea of tenements and in the countryside. Rather, he preferred to live in a single-family-

20. Neutra, *Survival Through Design*, 220.

house in a green suburb with fresh air and a forest or lake nearby, while staying close to the city center to advance his career and visit places like libraries, museums, concert halls, and theaters. In return, he was willing to accept a long commute. Accordingly, the two rented rooms he was most comfortable with at the time were located in the suburbs. One was in the Eichkamp housing estate in Berlin, at Königsweg 15, very close to the Grunewald forest and the Hundekehlsee lake; the other in the Chicago suburb of Highland Park, about a 20-minute walk from Lake Michigan, at 642 Vine Avenue.[21]

When Neutra and his family were first able to afford a house in 1932, they quickly understood that it would be a mistake to buy a lot where they would prefer to live—on one of the hills surrounding Elysian Park, Los Angeles. What they needed was not only a nice place to live, but also a suitable location for his architectural practice. In the end, they settled on the compromise of buying a small lot of about 400 square meters that was highly visible from the Silver Lake Boulevard, easily accessible from both Los Angeles and Hollywood, and still offered a beautiful view of the mountains and the artificial lake.[22]

Neutra designed a two-story house as close to the boulevard as permitted, using the full width of the lot. In 1939, he added a single-story building at the rear, again occupying almost the entire width of the property and creating a courtyard between the two buildings. Because the new patio lacked a view, he was unable to realize the concept of a nature near space that stages a distant view. It is probably for this reason that the first publications on the annex avoided discussing the courtyard and were accompanied by plans that refrained from depicting the main house.[23]

About 10 years later, around 1950, Neutra began to present the courtyard as the most important feature of the project and described it as an exemplary solution for dense construction on small lots, meeting the needs of people with limited budgets for spaciousness, privacy, and closeness to nature.[24] By the early 1960s, Neutra's understanding of dense courtyard housing had changed again. He now saw it primarily as a typology that prevents the construction of suburban neighborhoods of widely spaced single-family homes that consume too much land and generate too much traffic, resulting in air and noise pollution.[25]

Figure 3. Richard Neutra, VDL II, Los Angeles, 1963–65. View of the courtyard. The outdoor mirror provides a sense of spaciousness. (Photo by Julius Shulman, job 3989-57k, © J. Paul Getty Trust. Getty Research Institute, Los Angeles, 2004.R.10).

The main house burned down in 1963. When it was rebuilt, the floor plan was essentially retained because it had performed well and because it would otherwise have been prohibited to build up to the property line again. However, the courtyard façade, which had been designed in 1932 as a rear façade with high windows because the house was mainly oriented towards the lake and the boulevard, was now opened towards the courtyard. To make the courtyard appear more spacious and natural, Neutra refined his architectural means, bringing them closer to the simulation of nature. To allow plants to grow everywhere, he designed automatically irrigated flower boxes that float high above the courtyard. To visually enlarge the space, he strategically placed large outdoor mirrors **(Fig. 3)**.[26]

While Neutra initially saw the selection of the site and then the courtyard as compromises, he later came to see them as model solutions for building dense environments that do justice to human nature by integrating and enhancing external nature. This reinterpretation is in line with the simultaneous international trend of replacing suburban single-family homes with dense, low-rise typologies.[27]

6. CONCLUSIONS

Neutra believed that humans depend on nature for their physical and mental health. However, he does not see nature as something untouchable, but as something that can be improved, staged and, to a certain extent, even simulated without losing its positive effects. In suburban environments, and even more so in courtyard housing, he felt that such manipulations of nature were necessary to do justice to human nature. Yet he did not believe that it is possible to breathe life into architecture so that it becomes nature itself. It remains an artifact that must subordinate to nature by becoming a device for the perception of nature.

Do Neutra's buildings correspond to the concept of *the natural house* as articulated by Christian Norberg-Schulz, which loosely refers to Wright's publication with the same title?[28] In line with it, Neutra opened his buildings to their surroundings, destroyed the box, and used many natural materials. Also in keeping with the concept, but not discussed in this paper, he developed floor plans for an informal, free lifestyle and offered a refuge. However, unlike Norberg-Schulz and Wright, he fully trusted in the validity and universality of scientific methods, adapted his buildings to specific local conditions rather than to a local tradition or a genius loci, and was hardly interested in symbols. ■

ABSTRACT

Adapting modern public space to actual needs is a topic we discuss in a dialogue between different cultural and geographic realities in Chile and Germany. Both countries can look back on a history of adapting open spaces of modern complexes to contemporary needs.

Since 1960, Chile has implemented transformations in modern spaces following political utopias and social changes. The alterations pursued urban renewal through establishing "neighbourhood units" or through formalising informal settlements. The intensity of social needs and self-help dynamics has continued to influence original layouts to this day. Two specific examples of public space typologies in a Sites & Services settlement in Santiago illustrate how changes in public space made by users to satisfy their social needs enable different forms of public interactions.

In Germany, there has been a shift in appreciation for large scale modern housing complexes. In the 1990s, they were criticised as dinosaurs and even partially demolished in shrinking cities. Nowadays, their contribution to the increasing housing shortage, and their adaptability to climate change are appreciated. Given this context, the adaptation of open spaces has become all the more relevant. Two projects from Cologne show how upgrading helps to improve the living conditions of modernist housing complexes.

1. INTRODUCTION: OLD SPACES, NEW CHALLENGES

For publicly accessible space created in the zeitgeist of the modern movement to maintain its relevance as a site for gatherings and interactions, adjustments are necessary. While most modern complexes maintained their overall structure, public life in outdoor spaces has changed over decades. Nowadays —with changing cultural and ethnic compositions of city societies, with new habits concerning outdoor activities and communication, and with the desire of city dwellers to participate actively in co-producing cities, and with a changing climate— there is a growing necessity to adapt these spaces in Chile and Germany.

First, we focus on Chile's research on modernist public spaces in urban renewal through cases of neighbourhood units"[1] and Sites & Services-settlements[2]. These housing projects are widespread throughout Santiago and convey many experiences of adjusting the modernist vision to a concrete social context. In the 1950s and 1960s, Chilean architects, sociologists, and urbanists reenvisioned the role of public space in modern architecture by reorganising urban layouts, fostering different scales of sociability and implementing building methods, such as assisted self-construction.

Today, neighbourhood units and Sites & Services settlements are still valued in Chile, mainly because of their excellent urban standards. Studies on the adaptability of modernist complexes to today's social interactions and everyday practices in large housing ensembles like Villa Portales show that the community lacks appropriate spaces for their daily and meaningful activities, provoking tension and frustration within the surrounding community[3]. Another situation is evident in Sites & Services settlements built on a self-construction scheme. The original layout provided an excellent structure to develop a wide range of differentiated social interactions and feasible appropriations to promote public spheres.

Germany has pursued different ideas to improve the living conditions in modernist housing ensembles over decades. In the 1990s, they were often considered as "dinosaurs" and even partially demolished in shrinking regions. Nowadays, however, their potential is seen differently. Due to a growing housing shortage, they are acknowledged for providing large numbers of much-needed apartments, especially in metropolitan cities. Unfortunately, the overall conditions of many projects have suffered over decades due to a lack of investment in the building stock and in public spaces, leading to a deterioration in their visual appearance. Additionally, a one-sided occupation by disadvantaged households has led to an increase in social and ethnic segregation. The government has implemented various initiatives and funding programmes to address these issues —ranging from "quarter management" to "quarter development concepts" to "integrated urban development concepts"— and all efforts have involved collaboration with residents, owners and government officials. Nevertheless, most projects still struggle with a poor reputation and are marked by lack of order, cleanliness, and safety concerns along with important deficiencies in education, recreation, and cultural offers.

1. Neighbourhood Unit is a concept coined first by Clarence Perry (1920) that consisted in a settlement layout that included social infrastructure and green areas beyond dwellings. Perry also stated that a neighbourhood is a small-scale community where people know each other, share many of their activities, and provide a sense of belonging. However, the former modernist settlements in Chile followed Le Corbusier´s concept of *"Unité d´habitation"* which refers to an ensemble composed not only of dwellings, but also of a street layout, social and commercial infrastructure, as well as open space layout for leisure.

2. Sites-and-Services schemes are the provision of plots of land with a bare minimum of essential infrastructure needed for housing. These are government projects which go from a minimal level of a plot to an intermediate level of "serviced sites" to an upper level of "core housing" completed with utilities and access to community-based services. See: Sites and Services – and subsidies: the Economics of Low-Cost Housing in Developing Countries, 1987 in: Urban Planning and Design Branch, UN-Habitat, April 2012.

3. Rosanna Forray, F. Márquez, and V. J. Furio. "The Memory of Inhabiting Modern Architecture: Villa Portales, 1955–2010." *Latin American Perspectives* 44, no. 3 (2017): 64–82.

Despite the aforementioned problems, modern complexes are today appreciated for their adaptability to climate change: Their compact building structure, large public spaces, and flexible social service system make them pioneers in the debate on urban climate adaptation, sustainability and urban greening. Several German cities have cooperated with landscape architects and urban designers and upgraded the modernist settlements. Among them is the city of Cologne, whose neighbourhoods Chorweiler and Gremberg are described below.

Other countries have also gained experience in this area. Therefore, it is time for a global discussion: What changes are necessary to adjust public spaces to today's needs? How can they serve as multifunctional stages to accommodate a contemporary and dynamically changing public life? How can we adjust them to changing climate conditions, varying cultural and ethnic compositions of societies, changing outdoor activities and communication habits, and the desire of urban dwellers to participate actively in co-producing cities?

These questions were the main focus of Session 29: Adapting Modern Public Space to Actual Needs of the Docomomo conference 2024 in Chile. The session will explore Latin American and European examples and discuss inspirations for modern complexes waiting for adaptation.

2. CHILE: TRANSFORMATIONS IN SITES & SERVICES URBANISATIONS

The modernisation of the state in Chile in the 1960s cannot be closely tied to the production of modern urban layouts provided by Sites & Services settlements[4], which were conceived as a solution for deprived inhabitants coming from informal settlements. Despite the fact that various architects designed 466 such settlements between 1960 and 1980 in Santiago, there are similarities in the public spaces design. They included zoning of activities such as housing, sports facilities, education and health, as well as differentiating the streets and open areas based on their functions and promoting various scales of sociability.

Since the 2010s, "neighbourhood improvement programmes" have been implemented in these settlements, and contrary to the original characteristics, a scheme of state-assisted self-construction[5], the actual programmes did not consider community capacity of self-organisation and failed to integrate them into the city's public sphere[6]. Other studies underscore the potential of improving urban quality of life by defining the layout instead of undefining the built lots[7]. In the following lines, we present the study of appropriations in two kinds of squares made by dwellers and how they modify the original layout's idea of sociability[8].

2.1 APPROPRIATION: CLOSING AND OPENING TO THE PUBLIC

The main square contains a football field, which is centrally located and highly accessible from the adjacent main roads. However, the public character conceived for this space in the original layout was transformed by the appropriation practices of a private football club.

4. These settlements are called in Chile "Operación Sitio" settlements.

In: *Intersections - IV Interdisciplinary Congress of Research on Architecture, Design, City and Territory. Scales, Agencies and Territories in Latin America*. ed. Vicuña, M. et al. (Heidelberg: Springer, 2024 (in progress).

The small square is surrounded by dwellings that have only two entrances. Despite this communitarian character, the original urban layout anticipated for this space, the variegated neighbour's interventions, responding to different interests, ages, and genders, made this place more public.

Both transformations of the original settlement plan show the power of appropriations in public spaces. The study explores how to construct spaces with robust community structures without sacrificing the originally planned public sphere and the ability to include a wider public.[9] The adaptation of modern layouts presents the challenge of accommodating different forms of appropriation without altering the initial concept of a public space integrated with the city.

3. GERMANY: GREENING PUBLIC SPACE AND ADDING OFFERS FOR ENCOUNTER AND ACTIVITY

3.1 CHORWEILER: INTEGRATING OPPORTUNITIES FOR ENCOUNTER AND ACTIVITIES

Chorweiler is a large housing complex consisting of several high-rise buildings grouped around a central area in the north of Cologne. The complex was initially planned in the 1920s but was constructed only in the early 1960s and expanded further in the 1970s. Based on the concept of "urbanity by density," Chorweiler had long been praised for being the largest housing settlement in Western Germany.

In recent years, Chorweiler has made the news for its negative headlines. The housing stock and its surrounding public spaces cried out for renovation. This has led to poverty, conflicts and deterioration which place an additional burden on the already disadvantaged population. When affordable apartments became rare in metropolitan Cologne, Chorweiler garnered the city's attention. Eventually, in 2016, they initiated a renovation process supported by landscape architects and participation experts: "This time, by upgrading the public space of the complex, a better appearance and reputation should emerge, and with this, a better link of the residents' to their neighbourhood should be developed."[13]

In order to accomplish this goal, the office Urban Catalyst from Berlin collaborated with the landscape architect lad+ from Hannover to hold a participation process. Through several events and workshops with residents, different ideas for redesigning the public realm were developed in an iterative process. To the landscape architect, it was clear that at the end of such a process, the result would not be a spectacular design, but rather ideas for practical open spaces: "Chorweiler had enough of grand ideas from architects' desk. Now it was time for seemingly banal, however important things like elements with water, leisure- and outdoor sports facilities without entrance fees, space for seating, meeting and relaxing", says Martin Diekmann[10].

In 2021, Chorweiler's residents' ideas were implemented. The large, multifunctional Liverpool Plaza, the central Paris Plaza, and the adjacent Lyon Passage were redesigned. Although the renovation appears modest

9. Elke Schlack, et al., "The Public and the Community in Tension in Self-Built Urban Spaces"

10. Juliane von Hagen, "Dem Großen mit kleinen Schritten begegnen" *Deutsches Architektenblatt* no.11. 2021: 12-18.

at first glance, altogether 150 new trees were planted, 1.200 square metres of play- and sport areas were built, 450 metres of seating erected, and 130 bike parking racks constructed.

The large, centrally located Liverpool Plaza. which was once simply a large parking lot, has been transformed into a multifunctional urban plaza. Its considerable size and dimensions make it an ideal space for events, festivals and markets. To make the best use of the space, the landscape architects surrounded the central area with a border zone featuring trees, benches, and various recreational facilities. Outside of events, this zone is ideal for resting and sitting, and frames the large space giving it a human dimension.

The adjacent smaller public space, the Paris Plaza, is surrounded by public buildings and the communicative centre of Chorweiler: the shopping mall. For a long time, the mall was the most frequented spot. However, now, following its renovation, Paris Plaza has become more popular thanks to its water fountain, trees providing shade, and a large table. Since Paris Plaza functions as the "living room" of Chorweiler, its surface is made of red bricks resembling a carpet.

North of the Paris Plaza lies Lyon Passage. Like Liverpool Plaza also, Lyon Passage was also too large in its original design. Therefore, the landscape architects flanked its eastern side with seating steps and reduced its size visually. On its western side, a new boulder wall was built in conjunction with a playground. What used to be the windowless backside of the shopping mall is now a magnet for those who love physical challenges.

3.2 GREMBERG: GREENING THE PUBLIC REALM

The described project in Cologne-Chorweiler is an example of a modern complex that has been upgraded by altering the public space. A similar strategy was applied in Gremberg, a borough at the southeastern edge of Cologne. The starting point there was the intensive heat development in this neighbourhood. It is dominated by several types of multi-storey buildings with open spaces in between. Many of them, however, lacked amenities for social interaction, play or sport, as well as trees and vegetation for shade, and many areas were unattractive. According to a study conducted in Cologne, Gremberg suffered the most from increasing levels of heat resulting from climate change. Therefore, the city developed a landscape concept which became the basis for reimagining Gremberg's public spaces.

The internationally renowned office WES landscape architecture from Hamburg undertook this task of upgrading public spaces, creating green spaces, reducing sealing, implementing areas for various sports and play activities, and planting many trees[11]. Under the headline "ecological revitalisation of Westerwaldstraße" a residential road was converted into a pedestrian-friendly pathway with greenery. Like pearls on a necklace, three large green spaces now line up along this green corridor. All of them used to be unattractive, neglected spaces. After their redesign, they now offer easily accessible, peaceful seating areas in the middle of the housing stock, jogging tracks, playing fields, playgrounds, and challenging bike trails.

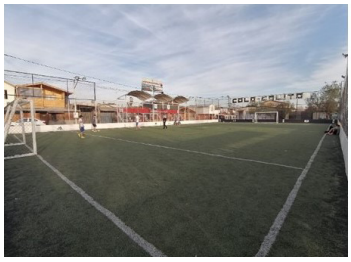

Figure 3: Vision for a Green Chorweiler (Source: Adrian Calitz und lad+, Hannover)

Figure 4: Cologne-Gremberg's Green Corridor Westerwaldstraße (Source: WES Landscape Architecture, Hamburg)

Similarly to Chorweiler, the planning was developed in close cooperation with the residents.

The list of projects aimed at adapting the urban environment in Germany to the increasing effects of climate change could be continued. Currently, the government of the state Northrhine-Westfalia is investing 250 million Euros in converting neighbourhoods into swamp cities. This involves disconnecting sealed urban surfaces from the mixed-water-sewer-system and increasing the rate of evaporation in situ[12]. Additionally, discussions are ongoing about greening facades and roofs. In this debate, modernist housing complexes play an important role, as they are considered ideal for these adaption measures.

4. CONCLUSION: BROADENING THE PERSPECTIVE

Although modernist complexes followed the same architectural and urban design ideas worldwide, the ensembles experienced different changes, alterations and adaptations over time.

Chile's public policies consider the regeneration of Site & Services settlements as a crucial area of focus. The goal is to care for the already existing "culture" of self-organisation. Today, the challenge involves adapting spaces to the increasing population and housing demand, especially in pericentral areas. At the same time, it is important to facilitate social interactions and cooperation between inhabitants of different generations and cultural backgrounds. Hence, adequate public space becomes a central element of the community and its public life.

The revitalisation and greening projects in Germany share similar goals. For instance, in Cologne-Chorweiler and Cologne-Gremberg, public spaces were reconceptualised and redesigned, leading to improvements not only in the public realm but also in terms of the living conditions, identification and care by the residents of the community.

In Chile and Germany, the debate on transforming the public realm of modern projects and modernist-inspired self-constructed settlements will continue. Although conditions and regional characteristics differ, the exchange of experiences makes the benefits visible: how healthy, safe, cohesive, accessible, affordable and sustainable living environments for large portions of populations can be sustained. ■

ABSTRACT

How can the parameters of public space influence the lives of the most vulnerable populations and promote sustainable ageing? Urban overheating requires a multi-layered understanding of climate change and its impact on cities' physical, ecological, social, and economic structures. This concern is at the heart of the ongoing multidisciplinary research project "Climate Adaptation for Older People Living in Vulnerable Urban Areas" (CAOP). Considering that the built environment is prone to disruptions brought by urban heat islands (UHI), this paper argues that while most spatial and social structures may experience these phenomena, they primarily affect the most vulnerable and thus, the design that takes their needs into account may produce a more inclusive, resilient, and adapted built environment. Therefore, the authors propose to analyse one of CAOP's case studies – the São Roque da Lameira neighbourhood in Porto, Portugal – as the laboratory to discuss the renovation and retrofitting measures of public spaces inspired by modern principles with a view to responding to present and future demands of the health, comfort, and well-being of the most vulnerable. The paper discusses the methodology generated within CAOP's research to identify morphological units with specific spatial characteristics. In parallel, the proposed process analyses the relationship between the spatial configuration and microclimate of urban spaces and community perceptions (through urban ethnography), thus crossing tangible and intangible dimensions to establish a new typo-morphological classification of a heat-prone neighbourhood. Due to their extensive green areas, this paper argues that such modern public spaces carry great potential to be adapted to creating age-friendly spaces, which could be enhanced through a comprehensive framework tool for multidisciplinary assessment. This tool will contribute to urban design research by highlighting principles to support sustainable urban strategies to prepare for change.

1. INTRODUCTION

The financed research project "Climate Adaptation for Older People Living in Vulnerable Urban Areas (CAOP). Designing a climate-responsive and community-based methodology" [PTDC/GES-URB/2038/2021] aims to investigate how planning and urban design can increase resilience in public – open, semi-open, and green spaces – urban places, considering that the collective use of these spaces can influence the health and well-being of older people living in vulnerable urban areas.

Climate change caused by urbanisation affects the urban thermal environment more directly than global climatic changes[1], influencing the entire population's quality of life, health, and well-being. It also impacts subsistence and the main infrastructure[2] [2], depending on the magnitude, intensity, and frequency of the event. Extreme heat is the one event that more seriously impacts the population, alongside ranges between night and daytime temperatures, landslides, extreme waves, excessive rain, storms/tornados, and extreme cold. In Portugal, and more specifically in Porto, the studies of Monteiro et al.[3] have highlighted the influence of the extreme heat phenomenon on the health conditions of populations. The literature also supports that older people are particularly vulnerable to the impacts of climate change[4,5]. Recognising the importance of developing a multidisciplinary approach to climate change, CAOP involves an integrated set of analysis methods of urban morphology, ethnography, and co-creation, as well as design and simulation methods, that will allow for the establishment of adaptation measures and facilitate their implementation. As the current percentage of adults over 65 in Portugal is high, a considerable portion of this population can be negatively affected by climate change. Against this background, the outreach of the ongoing research is expected to be high. The ultimate goal is to develop a "Handbook for Climate-Responsive and Community-Based Urban Planning / Design" that will contribute to creating accessible and inclusive environments. As part of broader research and an ongoing process, the present paper seeks to discuss the potential of modern public spaces in fulfilling that goal.

The design of public space integrated into planning emerges as an essential dimension that can contribute to the quality of life of older populations, mitigating the effects of climate change. Its importance is highlighted in international agendas. This complex framework requires the study of several areas of knowledge framed within a holistic approach to public space, considering the social, physical, and environmental aspects that interact and change over time. The solutions to climate adaptation may involve strategies that facilitate "socio-ecological" approaches that are more integrated into urban design. Therefore, from a holistic point of view, it is essential to establish strategies for designing public spaces, with the contribution of collective information from their users. References to public housing outdoor spaces, which are usually vulnerable to climate change impacts, serve as an example. Public housing estates, as social support mechanisms, tend to accommodate vulnerable populations (such as lower-income families, older adults, and dependent individuals with special needs, among others) but they are also strategic laboratories where public

decision-makers may implement qualification actions and inspire private investments and the broader production of the built environment.

The selected neighbourhood is situated in an urban rehabilitation area ('ARU', in Portuguese) of Corujeira, in the parish of Campanhã, Porto, Portugal.

The "Popular Housing Estate of São Roque da Lameira" was built by the Porto Municipality between 1959 and 1962 – during the "Estado Novo" authoritarian regime – under the "Improvement Plan for the City of Porto" (1956-66), promoting municipal housing for the lower-income population. This neighbourhood emerged in an area considered peripheral to Porto at the end of the 1950s. **(Fig. 1)**.

The design of the general site plan reflects the fragmented and low-standard appropriation of some of the guidelines of the Modern Movement and the Charter of Athens principles, whereby several medium-rise blocks are created and dispersed across generous green areas[6]. However, the modern plans encountered some problems regarding the design of the public spaces as they "pushed for innovation in indoor conditions while leaving the outdoor environment behind"[7]. This study aims to identify the specific vulnerabilities and potential in adapting public spaces to face extreme heat, while discussing the resources that can be activated to mitigate the impacts of climate change on older people.

2. A FRAMEWORK FOR ASSESSING PUBLIC SPACE ADAPTATION UNDER INCREASING HEAT

Evaluating the interplay between public spaces and the communities is mandatory to create opportunities for cities to reassess their role. Developing evaluation methods that capture the public space as a critical tool for adapting to climate change is urgent, given its inner capacities, qualities, and resources. This ongoing research addresses the morphological analysis of physical spaces from a relational point of view, considering different socio-spatial analysis solutions. Therefore, to understand the adaptive capacity of cities' public spaces in climate change, they must be regarded as social and ecological urban environments that implement and capture interactions between people and place. In this context, one might question urban morphology's influence on this adaptive capacity. As previously noted, cities will face different challenges and commitments in the future. Thus, if their adaptive capacity is improved, adjustments to new circumstances and changing conditions will be enhanced without significant disruptions.

The qualities of public space can be evaluated through its assets, in other words, through the assets of its tangible capital – physical and ecological – and of its intangible capital – social, institutional, and economic. The physical and ecological elements, regarded as tangible resources, can contribute to the functionality and resilience of public spaces. The intangible resources are also essential for the renewal of public space. From this point of view, existing resources represent a potential for the successful adaption of public space.

This section proposes an assessment methodology of the physical features of public space based on quantitative and qualitative criteria, using

the São Roque da Lameira neighbourhood as a sample. Several steps, including ongoing and future observations and interviews, are foreseen to validate the quantitative results and provide qualitative information to complement the analysis. The result of this assessment specifies the relationship between physical features and perceived qualities related to physical and functional vulnerability, considering the existing vulnerabilities and potential **(Fig. 2)**.

Focusing on public housing and its construction period, the outdoor space features and neighbourhood characteristics, this study identifies the physical/spatial vulnerability indicators of the units under study by considering predetermined urban form elements: street, neighbourhood, block, building, and open/green space **(Fig 3)**. More specifically, the analysis of the street system will provide the means to evaluate the degree of accessibility, centrality, and redundancy. Streets, squares, and green spaces will be analysed on the basis of proximity, porosity, and diversity elements. Following the methodological approach of Monteiro and Pinho[8], in this step, the spatial syntax will also contribute to unravelling the potential of the spatial accessibility of the street systems. Axial maps will be created, i.e., detailed maps of the spatial structure in the selected study areas[9]. The e-spatial analysis will also operate to evaluate the open spaces. After evaluating the correlations between the urban form characteristics and the social and environmental processes, the typo-morphological units will be classified, in line with the works of Eldesoky, Gil and Pont[10].

In operational terms, the Geographic Information System (GIS) will enable a study of the correlation between the values of the structural and configurational analysis and the results of the typo-morphological analysis, namely the correlation between i) the characteristics of accessibility to social infrastructure for the population over the age of 65 years, ii) the characteristics of semi-private and semi-public space, iii) the characteristics of public space and the results of the typo-morphological analysis. It should be noted that this framework will be completed with a microscale three-dimensional model using the Envi-Met programme. This is currently being developed by the Faculty of Engineering of Porto University under the same project.

Additionally, the qualitative assessment of the selected public spaces involves participatory processes – ongoing and future interviews and workshops with different agents, including the residents – and observations in the field, seeking to understand the influence of public spaces on people's quality of life and well-being, that could explain their *functional vulnerability*. Also, these observations and interviews will bear in mind urban design qualities such as imageability, visual enclosure, human scale, visual permeability, and complexity[11,12]. The assessment focuses on an open public space within a five to ten-minute walking radius (equivalent to 400-800 meters). The interviews will be conducted with key informants. Depending on the local context, the assessment will allow us to select, add, and prioritise specific indicators, given that a walking interview offers excellent potential to understand the population's connections with the place[13].

3. CASE STUDY FRAMING

This paper focuses on specific typo-morphological units of the São Roque da Lameira area, namely those corresponding to the construction of social multifamily housing. The "Popular Housing Estate of São Roque da Lameira"/São Roque da Lameira neighbourhood was built with public investment between 1959/61, having been expanded in 1965. (Fig. 3, 4)

Framed within the modernism tradition, the São Roque da Lameira neighbourhood comprises planned architectural ensembles with typo-morphological uniformity, structured by a regular road network. The urban fabric includes large plots of land, blocks, and buildings with 4 to 5 floors, often far from the street. In keeping with a number of multifamily housing neighbourhoods from the 1950s/60s, this neighbourhood displays a low level of integration, with less articulated public space areas and an urban frame more focused on the buildings than on the structure of the streets and their connections.

Nowadays these open spaces are quite degraded and poorly maintained, with unauthorised parking and a lack of shade and amenities, thus usually deserted

and uncomfortable. They show potential for the renewal of public spaces in terms of accessibility, proximity, and conviviality, meeting most people's health, comfort, and well-being requirements, and particularly climate change.

Climate studies of Porto point to an increase in the number of days of intense heat in summer and significant differences in temperature in different city areas14. The type of land occupation conditions the emergence of various microclimates, with the parish of Campanhã being associated with increased temperatures. It is also exposed to other vulnerability factors related to territorial segregation, resulting from both the rugged terrain and the ruptures caused by the fast lane that cuts through the parish territory, thereby contributing to the increase in social segregation within and beyond its area. This study, thus, expresses concerns regarding public space, which is understood as a device for the urban integration of the housing neighbourhood taken as a case study. Despite recent interventions (2013) in São Roque da Lameira neighbourhood buildings (mainly in the exterior envelope) and the installation of some public equipment in the surroundings (clotheslines, benches, sport equipment), this area displays weaknesses in the interplay between people and outdoor open/green spaces, hence discouraging neighbourhood relationships.

The former urban principle of building housing integrated into green areas also highlights the potential for minimising climatic stress. Reference to the documentation regarding the design of adjacent areas and equipment proves that the Modern Movement ideals expressed concern for promoting collective outdoor use spaces for recreational practice and social life. Some neighbourhood plans make the design of social facilities and amenities visible, such as access ramps to buildings and a children's playground with wooden equipment, reinforcing functional concerns.

While underlining the potential for adaptation of this modern movement's outdoor design principles and reclaiming their rearrangement according to the older adults' needs, the CAOP research project proposes to develop a responsive design manual by adopting a typological reconfiguration strategy that considers physical-functional, perceptive, and behavioural aspects, without erasing the modernism ideals to promote healthier lives.

4. FINAL REMARKS

This study delves into the adaptability of urban form and public spaces to climate stress, considering older people's health and well-being. Studies have demonstrated the importance of urban form in climate adaptability, exploring its role in mitigating the impacts of heat islands (IHU) and the influence that its features have on the tolerance of older adults to high temperatures.

This work addresses the indicators of urban form that allow for the assessment of its dynamic adaptive capacity. Notably, this paper proposes a methodology that targets the correlation between the urban form characteristics and measures associated with climate change adaptation and the population's perceptions of public spaces. It seeks to apply their correlation to a case study, the São Roque da Lameira neighbourhood, a morphological unit with modernism origins.

14. Câmara Municipal do Porto (CMP), *Suporte Biofísico e Ambiente. Estrutura Ecológica e Biodiversidade. Relatório de Caracterização e Diagnóstico, revisão do Plano Director Municipal do Porto*. (Porto: Câmara Municipal do Porto, 2018).

Making neighbourhoods more permeable to change, more inclusive and comfortable, with a high degree of interaction among residents, may be achieved through (1) the design of more comfortable and safe paths, (2) the elimination of architectural barriers, (3) the integration of different mobility modes (buses, cars, on foot) and (4) the design of small clusters of comfort in a context of accessibility and proximity, with amenities, trees, shade, resting areas and leisure spaces.

The notion of how "to live spaces" takes on greater importance, not only as a socialising factor but also for climate change reasons. It is assumed that open, green public spaces will become agents of urban and sociological transformation and prevent the effects of climate change. We believe that establishing principles based on determining the degree of influence of urban form characteristics on the resilience – adaptation and transformation – of typo-morphological units to extreme heat will enable a strategic approach to proposing new possibilities for the design of public space as regards thermal confrontation. Some challenges related to the different comfort levels in public spaces have required an integrated legibility process of the characteristics of the open/green spaces for enhanced social interaction toward climatic adaptation. In fact, it is acknowledged that modernism's ambition was to create healthier environments for future society, shaping inner comfort. Nowadays, the focus is expected to be on indoor and outdoor spaces, promoting their articulation and improving shared areas. ■

ABSTRACT

Plaza Perú is the only public space designed and constructed by Burle Marx in Argentina, a unique urban piece that, although reviled and forgotten for decades, still contains necessary values to rethink the culture of urban nature in contemporary habitat, in the context of those shortcomings that Buenos Aires City currently suffers from. Its history is well known, and the City Council commissioned the project to Burle Marx's studio, while the work was carried out by the Council services, and headed by architect Marta Montero. The project was developed to address the tension between industrial uses and residential expansion, in an urban environment lacking recreational spaces for children. The core element of the design, the so called "*muro-juegoñinico*", consisted of a large spiral playground for children, shaped like a sculpture to provide a safe area from the danger of urban traffic. The playground's backdrop was a mural inspired by the industrial warehouses nearby. Burle Marx's project included thorough research on local biodiversity and its potential for design in terms of geometry, space, colour, and time, taking into account their natural cycles. In spite of the fact that the project represented the perfect blend of urban landscape, biodiversity, painting, sculpture and architecture, the cultural incomprehension of this masterpiece led to its partial destruction by the City Council. While key elements of the Plaza have been destroyed, such as the "*muro-juegoñinico*" and the mural, the original layout and various elements of the landscape design still stand on site. In light of this distorted masterpiece, this paper aims to reflect on the challenge posed for its future and its role in the contemporary city: to document and demolish, to pave the way for a new project; or consider its restoration and reconstruction as a significant part of Buenos Aires city cultural heritage.

1. INTRODUCTION

The only plaza designed and built by Burle Marx in Argentina[1] is a key urban piece that, although reviled and forgotten for decades, still upholds the necessary values for rethinking the issue of the culture of urban nature in the contemporary habitat, addressing the shortcomings that the City of Buenos Aires currently suffers from. This masterpiece was distinguished for having achieved a perfect harmony between urban landscape, biodiversity, painting, sculpture and architecture. On the basis of this value, and considering its contemporary scope as architectural and landscape heritage, it is proposed to reflect on its restoration and reconstruction.

2. PROJECT AND RESEARCH

The City of Buenos Aires, in commemoration of the 150th anniversary of the independence of the Republic of Peru, built a plaza in an urban area with conflicting industrial uses and residential interests. The Plaza named República del Perú was inaugurated on December 12, 1972. The project was commissioned by then Mayor of the City, Saturnino Montero Ruiz, to the Brazilian landscape architect Roberto Burle Marx, who developed it alongside his partners, Haruyoshi Ono and José Tabacow. The work was carried out by the technical services of the Municipality of the City of Buenos Aires and directed by Marta Montero, an Argentine architect and landscape designer who had previously collaborated on various projects with the Brazilian master. Montero's role was fundamental for the realisation of the work, given that she had to face several challenges and difficulties, such as the lack of availability of some of the projected species, and a change of political administration in 1973 which led to a loss of interest and support. She defended the work of Burle Marx and sought to preserve its aesthetic and functional value, despite the modifications and deterioration that the Plaza experienced over the years.

The design was conceived to address the lack of children's playgrounds in the neighbourhood. At the heart of the project was a playful space modelled as a sculpture, surrounded by parterres located towards the perimeter of the block, with a mural inspired by the profile of the neighbouring industrial warehouses which served as a backdrop. The enveloping geometry of the spiral playground, named by the Studio as the "*muro-juegoniñico*"[2], sought to offer children a playful space protected from the dangers of the intense vehicular traffic in the environment. The urban promenade features, in it's most visible corner, a statue of Inca Garcilaso de la Vega[3]—considered the first cultural *mestizo* of America, since in his literary work he sought to assume and reconcile his two cultural legacies, the Inca and the Spanish. The piece contains heraldic symbology alluding to this nature and is surrounded by a semi-circular bench designed for contemplation.

The uses proposed for each sector —children's recreation, resting spaces for the elderly— coupled with the works of urban art —the sculpture, the mural, and the "*muro-juegoniñico*"— were integrated into a plastic composition with landscape design, creating, in the words of Arch. Montero,

W. Hüther; 1971: *Urban Renewal Plan Zona Sur; Plaza Constitución, Plaza Lezama, Plaza Garay* and *Chacra Saavedra*, for the Municipality of Buenos Aires City, led by Arch. J. Kurchan; 1973-1979: *Torres Canning* in association with Aisenson Studio. (Berjman,2014: 30-44)

2. It is a play on words: wall=muro, play=juego and child=niño. The suffix *-ico* is used in Argentina, not as a diminutive as in other Spanish-speaking countries, but as an indicator of the relationship of an adjective with the derivative base, with the sense of "characteristic of, similar to, typical of". In this case, it is applied to a noun: child. Possibly meaning: "play wall for children".

3. It is a replica of the artwork made in 1967 by the Peruvian sculptor Joaquín Roca Rey, located in the Giardino Piazzale Scipione Borghese, Villa Borghese, Rome.

"a children's oasis in full urban concentration, alternating green and dry spaces, plays and breaks."

The colour palette highlighted the different shapes and spaces: red, black, white, ochre, green and grey for the architectural surfaces; in addition to the polychromy of the native flora: the indigo of the jacarandas, the red of the ceibos and the yellow of the tipas, among several other native specimens arranged in favour of a plastic experience for the visitor.

Arch. Montero explained the design methodology applied, which helped to understand the way in which research and plastic sensibility were integrated:

> *When Roberto Burle Marx came to Buenos Aires to design the Plaza República del Perú, he was sixty-two years old. As his method consisted of working with the flora of the place, he took the trouble for months to study our native plants. We made excursions to places in the countryside where there was still some originality, because in Buenos Aires almost everything is exotic or imported from abroad. Fortunately, in some parts of the province, primitive landscapes are preserved. He looked, recognised, and chose the plant repertoire. At the time of planting, the municipal nursery did not have the species he had envisioned. I had to transplant adult trees from other* plazas*:* tipas, jacarandas *and* ceibos.[4]

3. DESIGN CONCEPT: GEOMETRY, NATURE AND COLOUR

In Burle Marx's work, formal variations can be distinguished over the years. These changes stemmed from a search that involved the study of a morphological repertoire that oscillated between the orthogonality of the right angle and the organicity of biomorphic geometry. As a design resource, during the 1960s, he made curves and straight shapes coexist, arranged in an orthogonal grid. By the 1970s, he had reached a level of maturity that prompted him to take advantage of all formal combinations, creating an eclectic composition by applying a variety of formal systems without transitions, combining contradictory qualities, as defined by Arch. Montero.[5] To design the Plaza, Burle Marx was inspired by the conch shells he collected when he was a child. During his visit for the inauguration, in an interview for a local newspaper, he explained:

> *The spiral is a shape that I like very much, because it is an organic shape, which is found in nature, in shells, in plants, in animals. It is a form that has movement, that has rhythm, that has life. I wanted to make a spiral that would be a playground for the children, that they could go up and down, in which they could have fun and learn at the same time.*[6]

In turn, his deep understanding of plant physiology and morphology played a key role in the design of the colour, textures and different spatial qualities for each sector of the Plaza, based on the natural cycles of the species throughout the seasons.

5. Montero, *Burle Marx, Paisajes Líricos* 1997: 11

6. Interview with Roberto Burle Marx, La Nación, January 1972.

4. THE INCOMPREHENSION OF THE PROJECT AND ITS PARTIAL DESTRUCTION

The lack of maintenance over the years, caused the *ceibos* to dry up due to lack of watering. Those were replaced by *lapachos*, which are a slow growing species, so that the Plaza gradually lost its shade. The play on colours that had been projected with the foliage and flowers never came to be. The mineral elements chosen for Plaza Perú —cobblestones and cement stained in ochre— became blurred over time.

Amid a lack of understanding of the project, negligence and cultural apathy, the "*muro-juegoniñico*" faced heavy criticism from some residents and politicians. Concerns were raised about the danger for children, the likelihood of them falling and getting hurt, and its potential to attract graffiti. There were also worries about the sandpit causing contamination and the entire structure becoming "a bolthole for tramps and addicts."[7]

In 1980, the adjoining shed that supported the mural was demolished, and fifteen years later, in 1995, Mayor Jorge "Topadora"[8] Domínguez ordered the demolition of the spiral volume, the core of this design, despite protests from residents, architects, landscape architects and defenders of cultural heritage. The demolition was met with strong opposition. Brazil's leading newspapers —*Folha de São Paulo, O Estado de São Paulo, Jornal do Brasil*— the Central Society of Architects of Buenos Aires, professors from the Faculties of Agronomy and Architecture and Urbanism of the University of Buenos Aires, as well as the Burle Marx office in Rio de Janeiro made their protests heard.

In 2001 the Museum of Latin American Art of Buenos Aires (MALBA) was inaugurated on the adjacent plot to the Plaza, a private institution that preserves and exhibits an outstanding artwork collection by the main modern and contemporary artists of the region, which is of great cultural impact for the city. Since MALBA became so popular, there has been a significant change in the way the plaza is used. The Plaza itself, which previously served as an area for children's leisure and for the elderly to relax, became a place just for passing through, a forecourt that is no longer comfortable. Occasionally, there are fairs and food stalls during the weekends, but during the week, it is an undefined space, provisionally active, but of little relevance for the neighbourhood on a day-to-day basis.

Despite these events, the "*muro-juegoniñico*" and the playful spirit of this Plaza still persist in the collective memory of the inhabitants of the city. Despite the fact that its construction was left unfinished and it became a vestige in ruins before its completion, the project conceived by the Brazilian master is latent, still awaiting the opportunity to be restored and reconstructed.

5. DOCUMENTATION & DEMOLITION VS. RESTORATION & RECONSTRUCTION

Faced with the current situation of the distorted masterpiece, this paper aims to reflect on the challenge posed for its future and for its role in the contemporary city. On the one hand, an option would be to survey, document and demolish, to make room for a new project, as has been proposed in the

7. In "Primer paso para ampliar el Malba bajo una plaza," *Clarín*, November 11, 2011.

8. Topadora=Bulldozer

project to expand MALBA by occupying the underground of Plaza Peru, thus finally erasing all vestiges of Burle Marx's original project[9]. On the other hand, another approach could be to consider its restoration and reconstruction not only as a significant part of the cultural and landscape heritage of the city, but also in terms of a contemporary project design paradigm to address two contemporary urban problems faced by the City of Buenos Aires. These include the lack of green spaces that boost urban biodiversity and the lack of public spaces intended mainly for childhood. These issues are on the public agenda, on the one hand in the Urban Environmental Plan (2008), which promotes improving the citizenship quality of life and providing access to and enjoyment of green urban spaces for all residents, while also preserving environmental, architectural, and cultural heritage. On the other hand, the Children's City Index (ICI), which evaluates the urban quality in relation to the availability of facilities required to guarantee childhood development within the framework of the International Convention on the Rights of the Child, National Law No. 26,061 and City Law No. 114 on the Comprehensive Protection of Children and Adolescents' Rights.

All these issues and design values are still present in this space and can be considered and recovered through the restoration and reconstruction of the original Burle Marx's Plaza Perú Project.

In addition, recovering this masterpiece which brought together common values to modern Latin American culture would be consistent with the current situation of the immediate urban environment, dominated by the MALBA.

Although the "*muro-juegoniñico*" and the mural have been destroyed, the original layout of the whole landscaping project is still preserved, as well as the pathways, the equipment - ribbon benches and linear benches-, the statue of the Inca Garcilaso de la Vega, the parterres and some of the species initially planted. Regarding vegetation, the only tree species that remained over the years is the *Jacaranda*, as the rest were replaced with other varieties such as *Palo Borracho* —a native tree—, Maple, Ash and Privet —EEI[10]—, which has had negative consequences in view of the contemporary issue of biodiversity loss, but also considering its significance in terms of the original project concept associated with the research on the American landscape identity.

In addition, it is important to consider that it is still possible to carry out archaeological surveys to find the vestiges of the demolished elements, recover the species still on site and replant those projected, based on the vast documentation preserved on the project and its materialisation.[11]

6. MATERIALITY VS. AUTHENTICITY: A RECURRING DILEMMA IN MODERN ARCHITECTURE PRESERVATION

Even though the theory and methodology adopted for the conservation of Modern Heritage should not differ with respect to those used for previous historical periods, many interventions carried out on these works have radically changed fundamental preservation principles: minimum intervention, maximum preservation of the original materiality, conservation *as it was found* and *where it was found*, reversibility and discernibility of the

9. "Project by Arch. Ott," *Clarín*, November 11, 2011.

10. Invasive alien species (EEI) causes loss of biodiversity, affecting public health, economy loss and degradation of historical and cultural values, https://www.argentina.gob.ar/ambiente/biodiversidad/exoticas-invasives/eei#:~:text=%20species%20ex%C3%B3ticas20invasivoras%20%(EEI,causes%20p%C3%A9rdida%20%of 20biodiversity

11. Preserved by Arch. Montero, by the Historical Archive of the City of Buenos Aires and by the Burle Marx Institute.

interventions carried out, ruling out reconstruction[12]. In fact, reconstruction has been a common practice in conserving the architectural legacy of the 20th century, ranging from modification of materials and constructive details to improving durability and the full reconstruction of lost works[13]. An in-depth analysis of this practice involves rethinking the concept of authenticity and considering its meaning in different cultures and historical periods. In these contexts, the authenticity of cultural heritage is not solely based on material originality, but also on its ability to guarantee the permanence of its essential values, such as historical and documentary significance, cultural and symbolic meaning, and design and craftsmanship[14].

The reconstruction of those demolished features of Plaza Perú should aim to authentically document its own constructive nature, form and texture and to recall the original space with scientific rigour. In this way, it could faithfully recreate the historical-aesthetic message of Burle Marx's project, ensuring that it can be passed down from generation to generation.

In addition, there are objective advantages that could help to reduce hypotheses about the original elements. This is because the project. Has been thoroughly documented allowing for its in-depth knowledge. Photographic records and drawings are available for both the project under construction and its subsequent stages, including demolitions and transformations over the years. Likewise, temporal proximity allows for contacting the authors or their collaborators[15], in this case the Burle Marx Institute and the director of the work, Arch. Montero, who has provided invaluable details about the design and construction process, and preserves detailed work documentation.[16]

Just as in the case of artistic assets, inappropriate interventions on *gaps* can distort and seriously affect authenticity.[17] In the case of Plaza Perú, those modifications after demolitions —including planting species over the void left by the spiral, that were not foreseen in the original project, such as *Palos Borrachos*, *Lapachos*, *Gramineae*, in addition to the changes in paving, lighting equipment and furniture— represent in themselves a false landscaping. A work stripped of its essential attributes cannot in itself be authentic, however authentic some of the preserved elements and species may be. Intervening in these gaps and recovering their functional values would not mean supplanting the author or falsifying his work. On the contrary, it can be a way of restoring its authenticity. As in the case of historic gardens, here, authenticity does not depend on the material originality of its elements, but on preserving its layout, its botanical and artistic wealth as a means to transmitting the sensory and aesthetic experience felt by the early users to future generations[18].

Finally, it is essential to understand that for the City of Buenos Aires, the recovery of this Burle Marx's masterpiece would be a cultural reparation. This would allow for a better understanding of its historical and cultural significance in relation to the contemporary habitat and the cutting-edge ideas associated with Modern Latin American Heritage. ■

REDEFINING THE ROLE OF PUBLIC SPACE AS AN URBAN CONNECTOR IN THE LORD COCHRANE HOUSING COMPLEX IN VIÑA DEL MAR

ANNA BRAGHINI
SCHOOL OF ARCHITECTURE AND DESIGN
PONTIFICIA UNIVERSIDAD CATÓLICA DE VALPARAÍSO

ABSTRACT

Designed by architects Juan Echenique, Alberto Piwonka and José Cruz, and built between 1961 and 1964 in the Recreo district of Viña del Mar, the Lord Cochrane Housing Complex was part of the new concept of urban development promoted at the time by the Housing Plan of the Corporación de la Vivienda (CORVI). The project proposed a housing density that would allow for the presence of green areas and the incorporation of various services, in favour of programmatic and social integration. It also envisaged the conformation of housing buildings of different typologies and sizes, a park and associated facilities: a plaza, a school, space for a neighbourhood council and community centre, sports fields, a parish church and car parks.

This paper aims to analyse the public space of the PLC, comparing the visions and models proposed by its architects in the initial design, and how its form continues to meet the current needs of its inhabitants. One of the main aspects that allow it to be defined as a pioneering project of modern architecture in Chile is the relationship between the typological experimentation of the housing blocks and the topography, characterised by a steep slope and a natural environment.

The conclusions reveal the peculiarities of an example of rational architecture, valuable for its link with the city's history, for its relationship with the landscape, for the challenge posed by the topography, and for the redefinition of public space. By rethinking the park's role as a factor capable of mitigating the dichotomy between public and private space, the housing complex could present an opportunity to develop urban regeneration strategies that could be applied to other case studies in the region.

1. INTRODUCTION

This paper presents the case of the Lord Cochrane Housing Complex (1961-1964) as a project that closely linked housing development policies and the postulates of modern architecture in Chile. It attempts to explain a complex that has gone unnoticed by critics and Chilean historical and heritage studies but nevertheless encapsulates and proposes fundamental issues about the political and architectural processes of the 1960s.

In 1961, the Corporación de la Vivienda (CORVI) launched a competition to develop a housing and community facilities programme on a hill in Recreo, Viña del Mar, to construct the Lord Cochrane Housing Complex. The land, which belonged to the Caja de Previsión de la Marina Mercante[1] (CAPREMER), was acquired by CORVI in an operation in which 10% of the housing would be given to the fund as payment for the land, and the remaining 90% to CORVI's affiliates.[2] The team made up of the architects Juan Echenique, José Cruz, and Alberto Piwonka won the competition, and the project was built by the construction company Nahmias Hnos. y Cía. The original project envisioned a social mix of buildings, with public housing for CORVI, housing for members of the Caja de Empleados Particulares[3] (EMPART) and housing for workers of the Caja de Marina Mercante Nacional (CAPREMER) and the Caja de Previsión de la Defensa Nacional[4] (CAPREDENA).

A review of the historiography of the Lord Cochrane Housing Complex in the context of modern architecture in Chile revealed no monographic publication is dedicated to the work. Similarly, there is little research on the development of public housing in the Valparaiso Region.

The study by Torres[5] highlights how, in the 1960s, the expansion of Viña del Mar was approached as a housing challenge in which the topography defined the limits of urban design and accessibility. However, at the same time, it enhanced possibilities for architectural design, as in the case of the Lomas Victoria Housing Complex in the Viña del Mar Alto area (EMPART, 1960) or the Lord Cochrane Housing Complex in Recreo (1961-1964, Piwonka, Echenique and Cruz). Ferrada's research[6] aims to address the main landscape issues related to the modern collective housing built in the city-port of Valparaiso between 1906 and 1976, highlighting how the complexes built between 1953 and 1976 were part of the work carried out by the CORVI to transform the housing problem into a matter of social and political rights.

An important precedent regarding the evolution of the public space of the complex is the doctoral thesis by Carrasco[7], which reviews the current state of seven modern housing complexes built in Valparaiso and Viña del Mar. It demonstrates how the appearance of new high-rise models on the hills had significant consequences on the scale of the neighbourhood and the city, such as the appropriation of the common heritage of the citizens —the view of the bay landscape— and a certain lack of control in the relationship between the built and its immediate surroundings.

However, no research has analysed the Población Lord Cochrane from the perspective of modern public space, comparing the visions and models

that the architects promoted in their design and how its form continues to meet the current needs of its inhabitants.

Questioning the current state of public space within modern housing complexes would help develop ideas for its conservation and possible adaptation. For this reason, it is necessary to ask: What has determined the abandonment of modern public space? What are the current needs of the inhabitants and the communities of the complex? How can the public space of the modern complex be adapted to these needs?

The purpose of the study is to analyse how the current public space differs from that of the modern era and to update the structuring role of the natural public space for the recovery and improvement of the complex. The research is based on primary sources from historical archives, magazines of the time, and the photographic record of the current state of the public space of the complex, as well as the historical and morphological analysis of the architectural attributes.

2. BETWEEN THE LANDSCAPE AND MODERN ARCHITECTURE

The space of Valparaíso is an architectural phenomenon that generates remarkable and profound human characteristics evident in its buildings. Beneath the city's picturesque space, many valuable architectural lessons coincide in essential points with current research: "To give the inhabitants the enjoyment of space, of the sun and a panorama to look at every day."[8]

This is how the *Revista de la Construcción* described the works of the Valparaiso housing plan at the beginning of the 1960s. The José Ignacio Zenteno housing complex on the Lechero hill, the Loma Victoria complex in Viña del Mar and the Lord Cochrane Housing Complex in Recreo were among those presented. What unites the complexes is their location in the amphitheatre of Valparaiso, whose essential characteristic is that the hills, the sea, the sky and the horizon, form that space.

Marina Waisman[9] argued that the work of architecture is inseparable from its environment, even more so than physically or conceptually, since architecture is conceived in an obligatory way from a location in a specific site, and this site and its circumstances constitute basic elements for the conformation of the programme and for the subsequent development of the work. For Waisman, identifying the typology of the relationship between the work and its surroundings is an element that provides access to an in-depth look at the ideological meanings of the form and reveals facets of the designer's thoughts on the urban project.

The general approach of the Lord Cochrane Housing Complex project responds to the site's topography and incorporates the natural space of the three ravines into its organisation by defining their urban edges. In particular, the three longitudinal residential blocks, through their concave and convex shapes, create a filtering area with the roads that define the site, thus creating a sector intended for parking. On the other hand, it leaves the three ravines present on the site intact, creating a green lung within the complex.

8. "Realizaciones del Plan Habitacional en Valparaíso," *Revista de construcción*, no.52 (September,1966):51-64.

9. Waisman Marina. *La estructura histórica del entorno*. Buenos Aires, Argentina: Ediciones Nueva Visión, 1972.

The complex was configured from two typologies of blocks: the curved, larger blocks, placed parallel to the elevation and formally insinuating the terrain altitude and with an external circulation system, and the smaller-scale linear blocks, placed in two groups perpendicular to the elevation and arranged in steps on the slope. As described in *Auca*,[10] the complex was organised in two sectors: one located in Valparaiso (sector 1, 303 flats), made up of two of the curved blocks (A and B), and three smaller-scale blocks (D, E and F); and another located in Viña del Mar (sector 2, 276 flats) made up of a curved block (C) and five blocks arranged perpendicularly to Manuel Rodriguez street.

Its location makes the Lord Cochrane Housing Complex an exceptional case in the relationship between private and public space. The complex allows us to analyse the evolution of the concept of public space according to modern postulates, showing a link between the conceived model and the built reality.

The centre of the complex was planned between blocks B and C. The school, gymnasium, church, market, and shops were to be located there. Later, after the first phase had been built, the construction of these buildings, except for the church and the Lord Cochrane School, was dismissed. It was, therefore, not possible to define the space of the plaza.

In the original design of the complex, the construction of a plaza was envisaged as an urban element that would represent a milestone in the planning, since it was considered to be an articulating space that would contribute to the improvement of the area and the well-being of the people, promoting the right to the city. In this sense, and following the postulates of the Modern Movement, the plaza, through its physical and experiential characteristics, determines the fulfilment of planning, the articulation of the urban grid and the interaction of the human being with the physical built environment, thus generating narratives of experience that nourish the rootedness, territoriality, identity, identification, legibility, accessibility, memory, connectivity and the improvement of the urban landscape. In the Lord Cochrane Complex, the non-execution of the community facilities and the plaza has transformed the natural space of the complex into the public space of the inhabitants.

What can be observed today is, therefore, a radical change in the definition of space, not only in relation to the surrounding urban fabric but also in the perception and sense of use that residents imprint on it. However, over sixty years of operation, interstitial, residual or lost spaces have emerged, which can be seen as unintended consequences of modernity and the total failure of an ideal of community space as such.

3. AN INTERIOR ALONG WITH THE CONTINUITY OF THE TOPOGRAPHY

The views from the top floors of the longitudinal blocks are powerful, with the older urbanisations below and the sea on the horizon. Faced with the task of building a new complex in a sparsely populated area like Recreo, the architects did not resort to the formal repertoire of the more common modern complexes, such as the prototypes of the neighbourhood units and towers,

10. Echenique, J., Cruz, J. and Piwonka, A. (1968). "Población Lord Cochrane." *Auca: Arquitectura Urbanismo Construcción Arte*, no.11 (1968):42-45. https://revistas.uchile.cl/index.php/AUCA/article/view/59004

but sought an answer in the more radical models of the modern tradition. Although not declared by the winning team, the Lord Cochrane Housing Complex shows, in the relationship that the buildings establish with the "void" of the public space, a certain analogy with Le Corbusier's Obus Plan (Algiers, 1932),[11] or with the proposal for the Naval School of the Institute of Architecture of the Catholic University of Valparaiso (IA-UCV, 1959). With the latter, in particular, there is a similarity in the spatial approach to the blocks, since the direction of the wind, the "cadet's routine" and the topography were the problems to which the project had to provide a formal solution. The observation of different acts on the site was the research tool.[12]

As Pérez points out, "form does not allude to the formal repertoire of architecture but rather to a specific configuration that responds to a given problem of the site."[13]

By analogy with the spatial structure of the Lord Cochrane Housing Complex, the IA-UCV project consisted of an open system that could contemplate additions and modifications in a clear logic of appropriation of the site, without altering its order. There was an idea of organic growth of the works at different scales; at the architectural scale of a house, as an ensemble, or an urban plan, the architectural approach longed for a system open to other processes, including additions, subtractions, and modifications, that would not disturb the organisation. There was a composition based on the external space, which was no longer what remained of the composition of the parts, but the empty space moulded the built one.

The particular relationship with the topography of the Lord Cochrane Housing Complex also suggests a connection with the Quartiere INA-Casa di Forte Quezzi project in Genoa. The architects' research, rather than defining the individual dwelling – not very innovative from a typological point of view, but interesting from the point of view of the relationship between individual and collective spaces – was aimed at developing a settlement model that would transform a sparsely populated sector of an isolated fragment, devoid of relations with the older neighbourhoods, into a structure that would establish an organic dialogue with the territory.

According to Argan,[14] the urban character of modern architecture was based on the idea that only by thinking of urban space is it possible to define the architectural form of each building within it. The Italian historian identified two dominant trends in modern European architecture: on the one hand, the "continuous projection," the "unlimited divisibility of space," the "search for quality" in the precise definition of the quantitative situation, and, on the other hand, a genuine "search for plastic formal evidence." Aalto's architecture was the first to achieve this synthesis, and Argan recognised its ability to perceive the geometric plan as a surface embedded in its environment, whose luminous condition was concretised in geometry itself, and which was located in the natural environment as a constructive, divisible and plastically articulated plane. Aalto intuitively understood not only that architectural form had to originate in the natural condition, but also, above all, that by locating itself in the natural condition, it had to radically transform it.

Examining the public space of the Lord Cochrane Housing Complex, it is easy to see that the arrangement of the longitudinal blocks also succeeds in shaping the space around it. Any observer who takes a closer look at the plastic form of the complex can see that it moves away from the purely formal character defined by a certain "aestheticism" of the complexes of the same period, such as the Recreo Alto Housing Complex. This is a precedent of the rationalist architectural criteria implemented in the organisation of settlements on slopes, in a context with rural qualities and in the process of densification, where the neighbourhood consisted of small houses perched on the hills and some chalets on the lowest elevation of the hill. Or as in the case of the Unidad Vecinal Loma Victoria in Viña del Mar, whose spatial organisation responds to the slope by defining a grid of perpendicular streets, with the larger linear blocks positioned perpendicular to the slope and the smaller blocks positioned parallel to it.

From 1973 onwards, the establishment of the military dictatorship radically changed social policy and signified the end of the welfare state. In the Lord Cochrane Housing Complex, the centralised administration ceased to function and each block began to be managed autonomously. This led to the separation of sectors and the initial closures of circulation and access to the blocks. In recent years, for security reasons, the communal areas have been progressively closed off with bars and, particularly on the ground floors of blocks A, B and C, the residents have closed off the public areas close to their flats.

4. CONCLUSIONS

The current state of neglect of the public space in the Lord Cochrane Housing Complex could easily suggest that the "experimental" nature of the complex has not lived up to modern expectations. However, when analysed in terms of the form of public space, the open space of the sclerophyllous forest shows an extraordinary relevance, despite the changing environmental conditions. Its density and the value of the forest as a green lung are flexible enough to accommodate new forms of public use. The public space not only acts as a unifying element in the layout of the residential buildings but also mediates their relationship with the surrounding neighbourhood.

The current relevance of the complex lies in its expansive green space, as a forest is integrated into the ravine, although unfortunately abandoned in certain parts. It is, therefore, urgent to propose an architectural and urban intervention to restore the semi-public status of those spaces that have been lost and have now taken on a private character. This category encompasses the common areas of buildings, courtyards and plazas that have been fenced off and locked up, and no longer function as public spaces. The proposal involves exploring strategies to reinterpret the public space of the Lord Cochrane Housing Complex as a nexus and promoter of urban identity, not only between the different blocks of flats but also with the urban fabric that surrounds it, favouring the neighbourhood use of the spaces. Undoubtedly, the public space of the forest plays a key role in the identity of the complex. ■

She holds a Master's in Architecture from the Pontificia Universidad Católica de Chile (2017) and a PhD in Architecture and Urban Studies at the Pontificia Universidad Católica de Chile and IUAV (2023). Currently, she is an Associate Professor at the School of Architecture and Design of the Pontificia Universidad Católica de Valparaíso. She has worked as an architect at the architectural firm CZA Cino Zucchi Architetti in Milan from 2009 to 2015. At the same time, she taught at the IUAV (2012-2016). Her field of study focuses on the history and criticism of modern architecture.

OPEN SPACES IN MODERNIST HOUSING COMPLEXES: URBAN AMBIANCE IN THREE CASES OF SANTIAGO DE CHILE

XIMENA ARIZAGA
PONTIFICIA UNIVERSIDAD CATÓLICA DE CHILE

#13

ABSTRACT

The research seeks to reveal the preferences of users for typological public spaces of the modern urban complexes considering the lessons that could be deduced from this way of densifying the city. The public spaces of three modernist housing complexes of Santiago de Chile (San Borja, Torres de Tajamar and Inés de Suarez) are disassembled, the uses are registered, and the ambiances identified to relate the spatial characteristics with the preferences of the users.

1. THE STUDY OF URBAN AMBIANCE IN THREE MODERN COMPLEXES OF SANTIAGO

In Santiago de Chile, as in other parts of the world, the mass housing complexes of the modern movement covered large patches of urban land. In these, a different logic to the traditional compact block of the Latin American city was configured, with important interior spaces, circulations and commercial plinths that were dissociated from the street and vehicular traffic. The research seeks to reveal the preferences of users for these public spaces — which prove to be highly versatile in their potential for adaptation — considering the lessons that could be deduced from this way of densifying the city.

The modern complexes were promoted by the welfare state during the government of Eduardo Frei Montalva (1964-1970) and were continued by the government of Salvador Allende (1970-1973). In 1965 the Urban Improvement Corporation, CORMU (1965-1969) was created to developpe a policy of "urban renewal", with the expressed idea of improving and renewing deteriorated areas of cities, increasing urban density, freeing up a high proportion of land and proposing a counterweight to the expansion of the urban sprawl. Since the creation of the CORMU, many complexes were built in the principal cities of Chile, and their residences remain in used and have a medium price in the real estate market, especially due to their central location. The public spaces of these complexes experienced deterioration, and this, in an unequal way depending to their typological condition. That is why this text focuses on exposing the search for an understanding of the different formal conditions that influence or could influence the evolution of the different pieces of public space that make up three modern housing complexes in Santiago.

The public spaces of San Borja (Bresciani, Valdés, Castillo y Huidobro Architects, 1969-1976), Torres de Tajamar (Bresciani, Valdés, Castillo, Huidobro and Prieto Vial, 1967) and Ines de Suarez (Barrenechea, Ehijo, Lawner, 1970) are disassembled, the uses are registered, and the ambiances identified to relate the spatial characteristics with the preferences of the users. The characterization of the spaces in four types: squares, connectors, shelters and remnants show that the shelters are the more used spaces and the ones with the featured ambiances, challenging the role of the square as a primary space. The proposition aims at understanding how using the concept of ambiance informs about urban micro-spaces. Ambiance is here understood as the emerging feature of the relationship between inhabitants' spatial practices, space and its sensory elements, since built environment becomes meaningful when used, inhabited and enhanced by individuals[1]. The study of the environment — in the sense of ambiance — would focus therefore on understanding the spatial and sensory devices that allow social practices to produce a particular and identifiable characteristic of a given space. The exposition delves into the spatial analysis of the possible motivations that lead to the choice of the shelter versus the square, by observing the use in practice. The choice of ethnomethodology, in that case, substitutes the study of perception per se by the study of the implementation of perception

1. Jean-François Augoyard Vers une Esthétique des Ambiances" in *Ambiances en Débat* ed Pascal Amphoux; Jean-Paul Thibaud, Gregoire Chelkoff, (Bernin: Editions À la Croisée, 2004); Jean-François Augoyard, *Pas à Pas*, (Bernin: Editions À la Croisée, 2010); Jean-PaulThibaud, *L'espace urbain en méthodes*, (Marseille: Editions Parenthèses, 2010)

in practice; aiming to understand how individuals' coexisting ways of perception are incorporated in daily activities and are their constitutive elements[2] A summary of the previous works that analyze the four typified spaces will be presented[3] and a detail of the observation of the inhabitant practices located in the squares and shelters will be exposed to relate them to the characteristics of the built space and its emergent perceptual properties.

2. THE SQUARES, CONNECTORS, SHELTERS AND REMNANTS

In previous research, the public spaces of the three chosen modern complexes were studied and cropped into four archetypal spaces that were identified and catalogued for each complex. The square is the prime space of urbanism since the Renaissance[4], and in the modern architecture of this large residential ensembles takes the most significative space between towers. In the three of them it is elevated from street. Especially in San Borja and Inés de Suarez it was conceived as a double square, one more public accessing to the buildings and an upper square more intime, conceived for the dwellers. In both cases, these upper squares are closed, denied to residents and the public by bars.

The connectors were the most singular characteristic space of these modern complexes, supposed to allege fluid access to the residential towers, and the expression of the new free experience of space. In Torres de Tajamar, the connectors are at the same level of the square and access, and maintain their condition of a corridor. In Ines de Suarez they were double: on the same level of the street and also on an upper level, connecting with the second square, now closed. In San Borja, connectors were conceived as a second possibility to experience and access the ensemble, connecting it with the city and at the same time, isolating the peasant from its realm. Nowadays, these connectors figure completely closed, and were only opened for exceptional days in the last years, showing its immense possibilities and the interest of neighbors[5]

The shelters are probably the most difficult to describe. It references to the haven created by the setback of the buildings in relation to the official street line. This is produced at the same time by the will of the modern complex to generate spatial rules differentiated from the traditional checkerboard pattern; and, by the need to solve the contact space with the pre-existing city. In this space the insertion of the modern complex within the urban realm is negotiated: the shelter is the space of Sola Morales' urban acupuncture (2018), the place where the gaps of the urban layout are harmonically combined. By resolving both the different heights of the plinth and the street and the distances with the pre-existing buildings, it offers a space for mediation. It is in this space where the suture between the modern complex and the urban permanencies are played. Adopting mostly the appearance of a bay, these spaces reveal to offer the most interesting possibilities for multiple uses.

Lastly, the remnants are constituted by the spaces with no conceived use. Mostly thought as gardeners or similar, there are abandoned and deteriorated. Especially present in San Borja withs different forms, leftover spaces are better solved in the other two complexes and particularly nearly absent in Inés de

Suarez. Remnants contribute to the unpleasant vision of the modern complexes and suffer from the unsolved administration of the common spaces.

The decoupage of the four typological public spaces is shown in the **Figure 2**, and examples of each space in the modernist housing complexes are shown below.

3. THE USES AND THE AMBIANCES

For each of the modern housing complex, the uses and the ambiances of each typological spaces were registered between 2018 and 2024, in different moments of the year and in different days and hours. Considering some regards for the research: the three ensembles have similar accessibility by underground and are connected with principal avenues, and despite their differences the three of them are inhabited by similar socioeconomic households. From the three, San Borja is the more centric and submitted by more metropolitan uses in its surrounds, and, Inés de Suarez is in the more residential context.

Principal uses in San Borja complex, without considering its environment are stationery shops due to the proximity with an architectural school, hairdressers, food locals and clothes' small locals in its plinth and a supermarket. In Torres de Tajamar, the corridors are surrounded by hairdressers, offices, small groceries, coffees, a pharmacy, a bar, a game-store, a cabaret, and a betting shop. The Ines de Suarez complex, in the observed years, maintains a martial arts dojo, laundries, a pizza restaurant, groceries, a greengrocery and offers since, new martial arts academies, coffees and a bakery.

The principal square in San Borja experienced since 2018 furniture changes: the space was implemented with flower pots, benches and a pergola. The locals in the borders remain, more deteriorated each year, giving this space an atmosphere of desolation and abandonment despite these efforts. The upper space once invested by an organization which tried to activate it, is now completely abandoned. The concerts, art and crafts market and its festive atmosphere has since disappeared. The points where the modern complex meets the ancient city experience different chances. Bordering the south and the school of architecture of the University of Chile, once a regiment building, a greengrocery used to occupy the sidewalk. In this shelter between the plinth and the road, between the modern architecture and the ancient building and trees, a neighborhood life used to accomplish. On the top of the plinth a coffee still takes place taking advantage of this balcony of the city. Unfortunately, the absence of the greengrocery with its friendly tenants, the choreography of the buyers, the smell and colors of the fruits and vegetables is gone, living the corner grey and gloomy.

The principal square in Torres de Tajamar remains nearly identic during these years, mostly empty, the octagonal kiosks that used to be empty have been occupied by groceries since. The square itself, seems to activate only for counted moments like the event produced in 2016, for the art fairy "espacios revelados" produced by the artists Courtney Smith and

Iván Navarro. Other spaces have little changes, the secondary square has been redesigned with a playground space, used by skaters; a new coffee appeared, the hairdressers are renewed. Still, the haven in the borders remain the more used, with an active life specially at lunch time **(Fig 3)**. The virtuous ambiance is here concentrated in the borders where Tajamar complex neighbors the other buildings and galleries.

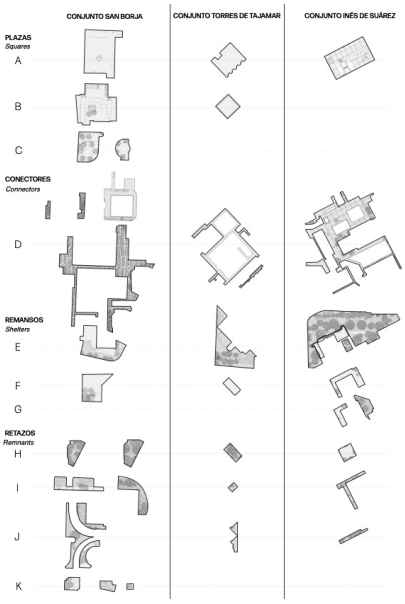
Inés de Suarez, is faithful to its residential character, small changes are multiple without a radical intervention: the greengrocery every Wednesday and Saturday improves its services, the locals change and the context remains. The use is more and more intensive in the central covered square: young people dancing their choreographies, children rolling (Fig 4); and, more people in the coffees located in the havens. Probably due to its residential condition, it retains a particular freshness that is benefited by the mix of elderly and young inhabitants who have arrived in this neighborhood and also in the surrounding area.

4. CONCLUSIONS: THE APPEARENT POSSIBILITIES OF ADAPTATION

For each typology of public space identified a different kind of possible uses and practices seems to be adopted. The sum of the formal space, the use and the practice traduce ambiances that seem to have similar bases in the three cases.

Connectors, even if the original possibilities were promising, remain in San Borja and Ines de Suarez truncated. The used connectors are mostly corridors in Tajamar and Ines de Suarez, where these spaces are opened and related to other bigger spaces: square or gardens. In these two complexes connectors keep a positive use and have a neutral ambiance. In San Borja where the principal connectors in the original project were the upper gateways, now closed, the connections are improvised spaces, gloomy, dirty and trapped between buildings.

Squares in San Borja and Torres de Tajamar are mostly empty spaces. In the second case, the space is activated when events considering an important group of persons take place. Currently space is occupied by timid persons lunching in a corner, young mothers playing with their children, or passers-by. In San Borja the space of the square is rarely activated, again, it is only with massive events when it takes sense: a volleyball match for example before the unfortunate last intervention[6]. Since the benches, pots and pergola was installed it only looks more uncleaned and uncomfortable: it's only a passing place. The covered square in Inés de Suarez is the most used, a comfortable floor attracts different activities specially for the younger: dance, roller, yoga. The groceries in the edges are active and needed by the neighbors. This mix of a needed commerce and a clean space seems to be at the core of success and a positive ambiance.



The case of the shelter has similar characteristics of use and practice for the three modern complexes chosen. In San Borja, this is the only

space in the plinth that invites you to stay **(Fig 5)**. A café has maintained this space for the years of observation, with tables that take advantage of both the shade of the oldest trees, planted on the sidewalk in counter bass; as well as the retreat from the noise and bustle of the street. In Inés de Suarez, each of the bays are occupied by a café, a restaurant, with tables and chairs. Away from the street and the vehicular traffic, here too, the space invites you to stay longer, it hosts a commerce that benefits from this condition of both edge and contact with the surrounding city. In the Tajamar Towers Complex the haven is the space of urban life, several cafes enjoy this space of friction with the city, a sort of small square is created in the distance from the building across the street. Every day it is possible to see this space occupied by an important number of people at lunch time, it is a sunny place separated from the noise of the main avenue and protected from the hustle and bustle of the street.

In conclusion the less flexible spaces turn out to be the largest: the squares. Around these spaces, commerce has less relation with the

7. In the San Borja Modern Housing Complex only the peace considered between Alameda Bernardo O'Higgins, Portugal, Marcoleta and the Parc are considered in the decoupage.

surrounding city, which probably hinders its development. This is particularly marked in San Borja, where the premises deteriorate year after year. In the Tajamar complex, although they maintain a certain standard, they have changed from being public places to offices. In Inés de Suarez, on the other hand, the residential character retains a certain flow of people loyal to the groceries and the principal use of the dojo.

In the other hand, most flexible spaces are the havens: the space of friction with the involving city. This condition favors the existence of a kind of commerce open to a public use, inviting the pedestrians to access and stay in the modern architectural ensemble. It's the space for social interactions, and urban conviviality. The coffees and restaurants usually installed in these shelters take advantage of the architectural form: where a fold is made in the form these premises take advantage of the space to install their tables, their chairs and invite the passer-by to sit down. ■

ABSTRACT

In the early 1990s, against a backdrop of social tensions, the Brussels-Capital Region implemented Sustainable Neighborhood Contracts (CQDs, *Contrats de quartiers durables*) to encourage projects respectful of the existing urban fabric and socio-ecological conditions rather than resorting to prevalent demolition-reconstruction methods. These contracts, funded regionally and implemented at the municipal level, target specific neighbourhoods grappling with social, economic, and urban challenges. Their focus includes public property projects to enhance housing, revamp public spaces and infrastructure and establish community facilities. Additionally, they incorporate socio-economic initiatives to stimulate local societal and economic vitality, emphasizing resident participation.

CQDs have evolved over 25 years, adapting governance and strategies to address the region's diverse needs, extending their scope to new territories. The CQD Peterbos stands out by exclusively targeting a large post-war social housing estate, departing from earlier approaches focused on older traditional urban fabric.

The paper discusses the transformation of Peterbos Park (1968-1981), the Brussels' largest social housing estate built on the outskirts of the city centre, emphasizing the need for urban renewal tools to align with the unique social, morphological, and architectural aspects of such context. Successful intervention requires deep engagement with local communities and a thorough understanding of the site's history and original goals. The challenges of intervening in large-scale social housing estates located outside city centers underscore the need to adapt CQD objectives and resources.

This contribution is an opportunity to put post-war social housing intervention policies in Brussels into perspective, including in terms of architecture practices.

This contribution is based on the results of the "LOGOS/RES-E3" research project (*Le logement social comme resource : énergie, économie, environnement social*)[1].

1. INTRODUCTION

In Brussels, as in many European cities, the post-war period was characterised by urban modernisation and economic development. Numerous districts, were renovated, completely rebuilt, or built ex novo as part of ambitious urban development projects, sometimes by using questionable methods. It was only with the regionalisation process initiated in 1989[2] that Brussels embarked on a revitalizing campaign of its historic neighbourhoods, spurred on by citizen protests highlighting persistent social divisions and calling for more humane intervention that would be more respectful of the existing urban fabric.

Born in the early 1990s, the Neighbourhood Contracts (CQs, *Contrats de Quartier*), which would evolve into Sustainable Neighbourhood Contracts (CQDs, *Contrats de Quartiers Durables*) in 2010, are urban renewal tools developed and implemented by the Brussels-Capital Region with the aim of providing comprehensive solutions in neighbourhoods facing social, economic, and urban challenges.

2. DEFINING THE CONTOURS OF URBAN REGENERATION

Inspired by the scheme introduced in France in the 1980s, known as for Neighbourhood Social Development (DSQ, *Développement Social des Quartiers*), the Brussels tool is based on 4 key principles: (1) Actions on different levels: housing construction and renovation projects are combined with the redevelopment of public spaces and various initiatives to promote social cohesion; (2) Collaboration between stakeholders: the Brussels Region, as subsidising authority, and the municipalities are the main players in the partnership, but the dynamics to be put in place also involve the CPAS (public centres for social assistance), public interest organisations, private investors, associations and local residents; (3) Multiple scales of interventions: the block and individual building policy is extended to a neighbourhood policy, thereby establishing the boundaries of a new administrative unit; (4) A given timeframe: the program is being developed over a four-year period, extended by two years to finalise the implementation of the operations. The new urban regeneration policy is therefore defined as a reciprocal commitment - hence the term 'contract' - to draw up and implement an integrated programme, negotiated collectively, in a given area and over a given period.

CQDs are selected based on a priority zone that has undergone various name changes over time, such as ZPR (*Zone à Protéger et à Rénover*, 1984), EDRL (*Espace de Développement Renforcé du Logement*, 1993), and EDRLR (*Espace de Développement Renforcé du Logement et de la Rénovation*, 2002), evolving into Urban Revitalization Zone (ZRU, *Zone de Revitalisation Urbaine*) in 2012, amended in 2016 and 2020 to incorporate socio-economic indicators, extending beyond the condition of buildings. This adjustment allows for a redefinition of priorities and, consequently, a reshaping of the geography of the most vulnerable neighborhoods. These are gradually forming a contiguous space, commonly known as the 'poor crescent' of Brussels, contributing to the "representation of a continuous,

2. In 1989, Belgium undertook a process of regionalisation aimed at transferring political powers from the federal institutions to the Flemish, Walloon and Brussels regions, in order to better respond to the country's regional and linguistic aspirations.

unified territory of poverty and blight, at the core of a Region whose other territories remain relatively unknown and under-investigated"[3].

3. BEYOND 'CELLULAR THINKING'

Over the last 25 years the tool has evolved both in its mechanisms and modes of governance to address the region's contemporary challenges, refining its objectives through a succession of organic ordinances and diversifying consequently his resulting urban production. Thanks to a constant interest for innovation, this instrument has become a veritable "machine for renovating the city"[4] and which today extends to more remote areas in the second ring of the Brussels region. The urban regeneration policy that initially consisted of successive interventions in neighbourhoods as "disconnected cells"[5], has gradually evolved into a more global policy **(Fig. 1)**.

In particular, a new ordinance adopted in October 2016[6] proposes new tools to go beyond 'cellular thinking'[7] by promoting better connectivity between 'pockets', working on connections and interfaces.

Another output of this ordinance is the inclusion of new types of neighbourhoods in the ZRU perimeter, including social housing estates. Within this framework, the first CQD whose perimeter was defined exclusively around a large social housing estate, was Peterbos Park.

4. PETERBOS PARK BETWEEN THE LINES

Built in Anderlecht between 1968 and 1981, Peterbos was designed as an inhabited park to support the densification of this district on the outskirts of Brussels, through a logic of green continuity[8] and car accessibility. Nowadays, it represents the largest social housing estate in the Brussels Region, with a total of more than 1,400 dwellings on 17 hectares, representing around 4,000 inhabitants, almost all of whom are social tenants.

Managed by two distinct public housing companies[9] who have taken turns to carry out renovations, some of them major, without any long-term strategic vision, the site has gradually lost any overall coherence **(Fig. 2)**. For many years, it has received a rather negative reception both from the public and its own residents. The park is regularly in the news due to incidents of delinquency that have gradually tarnished its image. In addition, public and open spaces have suffered particularly from neglect and lack of maintenance, leading to a loss of interest and attractiveness to residents. And yet they are an essential feature of large housing estates as they are the main meeting places for residents, the first "commons", and therefore a key issue.

However, the site has outstanding features. Designed in the spirit of a 'park system'[10], Peterbos is an important landscape piece in a network of green spaces on a metropolitan scale, linked by the 'green promenade' that borders the site to the north. The concept of a residential park is embodied in the spatial organisation of the site and the layout of the buildings. The distance from the road allows the green to take centre stage in the relationship with the outside world. This 'open-order' urban feature, which is the identity of Peterbos Park, has remained largely untouched until now.

9. Public social housing in Brussels is overseen by the Brussels-Capital Region Housing Company (SLRB, *Société de Logement de la Région Bruxelloise*), which supervises Public Housing Companies (SISP, *Sociétés Immobilières de Service Public*) of which there are currently 16 spread across the Region. These entities manage housing units and ensure access to social housing for low-income households, in collaboration with public authorities.

Furthermore, it is representative of a widespread practice in Europe during the post-war period.

5. RECREATING LINKS BY THE GROUND

As part of the CQD diagnosis, the municipality commissioned Studio Paola Vigano and vvv office to produce a masterplan aimed at "recreating links" between the various entities on the site, but also beyond.

Their analysis suggests that the ground "is a monumental base-ground, with low walls, slopes, staircases, inspired by the Italian Renaissance Garden"[11]. Indeed Peterbos Park is built on a slope, and the design of its spaces is based on a meticulous topographical design. The ground project, established subsequently to the site development plan, is uniformly based on functionalist principles of flow separation: cars remain at the edge of the site, in parking areas arranged around the main access roads. As at the Cité Modèle (R. Braem, V. Coolens, L'Equerre, R. Panis, Groupe Structure, J. Van Doosselaere, 1956-1972), the ground beneath the towers is levelled to create a unified plateau, resulting in differences in height, naturally separating pedestrian areas and car parks. The park features pathways cross the area at a distance from the buildings, creating green spaces at their base. These distinctive characteristics are primarily evident in the initial phase of site construction, whereas the later-built southern part appears to be more fragmented.

Similar to other social housing developments built at the time, financial and logistical imperatives have gradually eroded Peterbos' foundations, leaving the neighborhood devoid of social amenities and essential businesses. What was intended to be a model inhabited park has progressively transformed into an isolated enclave. The progressive development of regional road infrastructure around the perimeter reinforced the rupture and today contributes to the site's introversion and thus, his negative perception.

Based on this diagnosis, the masterplan's proposal aims to extend the identified qualities and the spirit of "monumentality" outwards, towards the city, while at the same time bringing the ground of the city into the Peterbos. This ambition is reflected in the creation of a system of squares located on the edges of the site, "aiming to transform physical or visual 'barriers' into potential places that reinforce the link with the natural ground, the slope of the valley"[12]. The most significant project involves the enhancement of a new entrance in the east of the park. Based on a deep analysis of existing mobility dynamics, it aims to develop a genuine multimodal platform along the main boulevard, which currently acts as a border. At the western part of the site, a similar approach is being adopted with the creation of a local-scale square connected to the neighbouring *Cité Jardin*. Optimization of the parking areas promotes new public spaces whose clarity is ensured by uniform material choices, providing a new coherence and identity to the site.

6. NEW CENTRALITIES

Another specific strength of the CQD tool is that it is based on involving local residents in the planning of their living environment. Participatory

11. Paola Vigano & vvv architecture urbanisme, *Peterbos. Vivre le parc, habiter la ville*. Masterplan, 2020, 21.

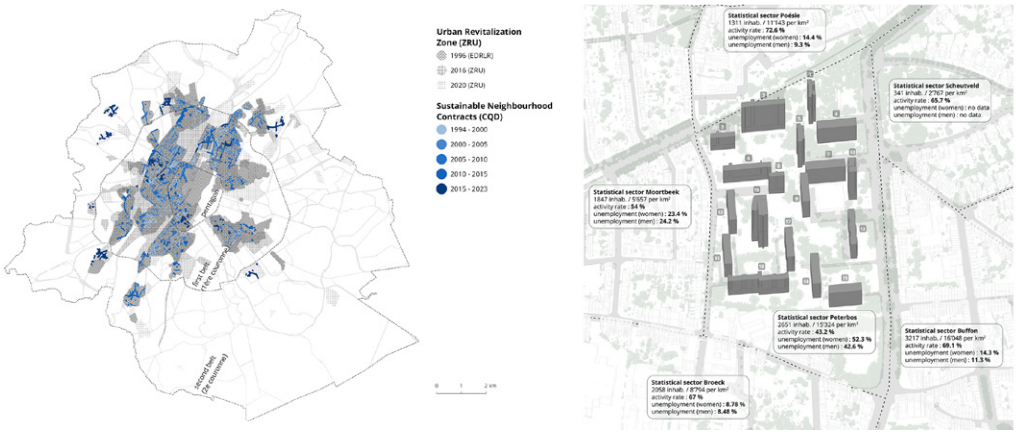
12. Paola Viganò & al., op cit., 162.

workshops highlighted the need to move away from the monofunctionality of the neighbourhood, firstly by integrating projects that could attract an external public to the site, and secondly by opening up the possibility of creating employment within the Peterbos. Indeed, the site is currently inhabited by a highly marginalized population with a high unemployment rate **(Fig. 3)**. With the support of the masterplan, the CQD has undertaken: (1) the requalification of the ground floors of the buildings and (2) the construction of new social facilities, initially planned in the first plans of the site but never really achieved[13]. The CQD therefore plans to build a nursery and a facilities hub, itself designed as one of the park's new centrality. This hub is designed to integrate into the landscape, transition smoothly with the relief through adapted features, and ensure the fluidity of movement. His rooftop terrace provides a panoramic view of the surrounding.

7. LIMITATIONS & ADAPTATIONS OF THE CQD TOOL

While the CQD and its masterplan strive to reintegrate Peterbos into society via social and spatial initiatives, it is evident that this approach alone won't address the deeper social challenges emblematic of many housing estates.

Indeed, by concentrating on the public space as the only area for action, Studio Paola Vigano and vvv office highlighted a first limitation of the tool. They are aware that the space for manoeuvre in such a context is both wide and narrow.



> *Wide, because it fulfils a plurality of practices, ordinary and extraordinary: public space concerns everyone. Narrow, because our project does not have the power to transform the inequality concentrated at this site, which is linked to past decisions that have turned out to be ineffective from the perspective of social integration.*[14]

Another particularity of a site like Peterbos lies in the multitude of actors involved in its slow and gradual transformation. The CQD must accommodate (but can also rely on) projects led by other stakeholders benefiting from their own specific budgets, particularly for building renovations carried out by Public Housing Companies (SISP), which began in 2010, ten years earlier. It is clear that the qualities of the site highlighted in the masterplan have always been overlooked in SISP decisions. From the beginning, and in response to years of neglect in maintenance, these have favoured interventionist attitude, deep renovations, leading to the detriment of the site's integrity and the complete metamorphosis of its buildings.

In addition, this decision-making complexity is not without consequences for local residents. Researchers from the SOHOLAB project (2017-2020), whose main objective was to explore effective ways of involving residents in the regeneration of large social housing estates such as Peterbos, have identified two significant impacts arising from the overlapping of actors and funding sources, as well as the associated temporalities, along with the lack of a comprehensive vision of the site on the part of the residents.

Figure 4. Overlap of stakeholders and tools in Peterbos Park. © Authors, 2024.

On the one hand, the multi-actor regeneration of the site created a lot of confusion. The missions and structure of the different agencies are hardly understood. On the other hand, the ad-hoc interventions, consultation processes without actual interventions, malfunctioning transfer systems during renovation works and poor communication about renovations, contributed to feelings of powerlessness regarding the resident's living situation.[15]

When we consider both the shortcomings of the Peterbos site and the efforts undertaken by the CQD to address them, alongside the recent adaptations in the CQD tool, doubts raise about its suitability for addressing the challenges of a social housing estate. Indeed, by concentrating the intervention efforts of a CQD exclusively within the

15. Maranghi, E., Cognetti, F., Ryckewaert, M., Aernouts, N., Mosseray, J., Lefrançois, D., Wachter, S. & Labied, N. *"5 themes from urban living lab experiences in large-scale social housing estates"*, (Brussels: Soholab, 2020)

perimeter of a large social housing estate, is there not a risk of repeating the same mistakes as the initial project? As the challenges of these neighbourhoods are not isolated - they are intrinsically linked to the wider socio-economic and urban dynamics of the Region - extending the scope of the CQD to the surrounding areas, as recommended, and favouring a broader approach could have significant benefits.

8. CONCLUSION & PERSPECTIVES

While it is important to distinguish between the renovation of buildings, carried out by the Public Housing Companies (SISP), and the socio-spatial actions as part of the CQDs, it is clear that by operating at the same time in the same area, i.e. large social housing estates, the actions overlap. The resulting project is a fusion of their respective tools, even if they are, most of the time, not really linked (Fig. 4).

In this respect, an analogy can be drawn between the observations made in this article about CQD tool and the intervention policies on social housing buildings in Brussels.

First of all, the overlapping of actors and funding sources, while inherent to the Belgian institutional system, is not beneficial. The Peterbos' transformation will have lasted 20 years. The fragmented interventions, both spatially and temporally, not only have had detrimental effects on daily life and resident trust but have also led to an irreversible loss of architectural coherence and quality.

Secondly, the CQD mechanism is often politically influenced by power dynamics between the regional authority with its own objectives, and the municipalities, which defend their autonomy. A comparison can be made with the issues surrounding the renovation of buildings, which often involve a blend of conflicting quantitative goals regarding energy efficiency, environmental impact, logistical and economic limitations, cultural values.

To address these issues, it would be useful to rethink the CQD tool with a more integrated approach, bringing together all stakeholders to establish a comprehensive strategy based on a common diagnosis and action plan before any renovation. In the case of large social housing estates, this would facilitate greater interactions between the ground floors of buildings, owned by the SISPs, and the public spaces owned by municipalities, which they help to animate.

Finally, it is important to keep in mind the limitations of urban planning as an action tool. Just like architecture, it can't be solely blamed for the social issues within it. Nor can it claim to solve social divides.

More generally, it would be interesting to move beyond well-meaning rhetoric and address fundamental questions about the position and significance we envision for these neighborhoods in our future societies. To continue fulfilling their social role while maintaining their original identity, large-scale social housing estates requires, above all, a political stance. ■

ABSTRACT

The focus of this paper is to debate modern residential housing developments from the point of view of management, with a particular emphasis placed on social housing developments, especially in Latin America, debating the forms of appropriation and social organisation by the state or by the residents. Originally built as part of social welfare initiatives—which in Latin America have remained incomplete—housing projects have had issues of maintenance, management, and occupation from the outset. Unlike European cases, these developments still have a small, but growing, critical fortune in terms of heritage, management, memory, and social appropriation. In most cases, the states that built them and were originally responsible have sold the properties to the residents. These residents now must deal with the challenges of managing the buildings, the common spaces, and the transformations, while at the same time preserving the memory of the past of these places. Therefore, the issues related to the occupation, management and appropriation of housing are huge challenges for modern social housing in Latin America, which this contribution seeks to explore from various perspectives.

1. INTRODUCTION

The development of modern architecture and urbanism between 1930 and 1979 had a profound impact on the urban structure of Latin American cities and metropolises. This impact is visible today in the large neighbourhood units and in the large portions of the urban fabric that was built on behalf of modern ideals. The housing developments built in the second post-war period are important examples of the realisation of modern ideas in Latin American cities. Furthermore, they have already been extensively researched from many perspectives, especially in the international context. For Miles Glendinning, the mass production of social housing for low-income citizens, usually in high-rise towers or horizontal blocks, was a global phenomenon. It became a model of housing and city adopted in cities around the world, from Moscow to Buenos Aires, from Stockholm to Singapore, combining elements of state and modern architecture.

It could be noted that a correlated phenomenon of broadening the bibliographic bases on 20th century architectural production has also been taking place in other Latin American countries. If in the 1990s Roberto Segre had stated that the social housing built by the emerging industrial proletariat was inadequate and insufficiently addressed in most studies on Latin American architecture, there has been a shift in this trend in recent years. There has been a push for studies that focus on local cases as there was in Brazil, resulting from the increase in postgraduate programmes, and greater stimulus for publication and the historicisation of 20th century architecture. On the history of housing, works by Anahí Ballent, Francisco Liernur, Graciela de Garay, Ana Patricia Montoya, Umberto Bonomo, Flávia Brito, Enrique De Anda, Manuel Ruiz, Rosa Aboy, Sharif Kahatt, José Huapaya Espinosa, Camila Ferrari, Nilce Aravecchia-Botas, Diego Franco and Dinalva Roldan have contributed to a better understanding and interpretation of production in specific cases such as Argentina, Venezuela, Chile, Peru, Colombia, Mexico and Brazil.

There are still many aspects related to the residents, their socioeconomic characteristics or the forms of organisations that were implemented in the neighbourhood units of Latin America that have not been thoroughly researched. The session titled "Management and community life of Latin American neighbourhood units" analyses the development of the large housing complexes built in Latin America between 1930 and 1970. For almost half a century, critiques of this architecture have focused on its architectural, cultural, and social homogeneity, both in the Soviet world and in Western countries. However, empirical research has demonstrated the variety of post-war public production in some parts of the world, overcoming the consensus of unity, monotony, and lack of diversity. In contrast, the experience of modernity in public housing was much further from uniform monochrome, and much closer to embracing overall diversity and complexity in its colours, forms and social composition.

2. HOUSING AND ITS HERITAGE DIMENSION

The solutions for housing on the continent have been diverse and widely debated. If they were built on the basis of compromises between the state and

modernisation in the mid-20th century, they persist as a legacy in contemporary times, revealing and interpreting the ambiguities of the modern project, the tensions over its realisation, its forms of constitution and urban occupation and, finally, the appropriations and reappropriations in its trajectories.

In Europe, the discussion surrounding the legacy of social housing from the 1940s to the 1960s has been intense since the 1980s. This was triggered by the crisis of the welfare state, which redefined the parameters of state action in the field. Important experiments in research, preservation and restoration have taken place in various European countries such as Germany, Italy, England, France, and the Netherlands, and these have garnered the attention of residents, public authorities and interested parties. The ways in which this legacy has been interpreted have varied, both in terms of the character of the complex and the country. From the iconic structures of the inter-war period to the mass complexes of the post-war period, a wide range of considerations have been articulated as a legacy for future generations. Responses have ranged from mass demolitions to the challenges of integrating migrant populations into the suburbs, as well as exemplary cases such as Berlin's Unité d'Habitation. Moreover, UNESCO's consideration of iconic Berlin complexes as world heritage sites demonstrates the diversity of paths and possibilities that housing complexes present as part of our heritage.

In Latin America, housing projects and neighbourhood units have played a significant role in housing policies. For many, however, they have remained incomplete or frustrated achievements, while for others, they represent hope for effective state action on the issue. All the same, it seems correct to state that they remain as documents of a historical process that provided housing for workers during brutal transformations in labour relations, urban territory occupation and social relations. Their permanence in contemporary Latin American cities and the discussion of their legacy for future generations remains a relatively unexplored subject, particularly if we consider the joint meanings of this production. Changes in lifestyles, patterns of working-class domesticity, urban transformations, new labour relations and the role of the State in Latin America when addressing the issue of social housing are all part of a larger body of questions and research responsibilities when considering this legacy.

3. COMMON SPACE AND THE CHALLENGES OF COMMUNITY

In the second post-war Neighbourhood Units, the garden city layouts were replaced by green areas not crossed by vehicular streets, therefore creating macro blocks penetrated only by pedestrian access pathways to the apartment buildings. In these neighbourhoods, land occupation varies between 20% and 40% of the land available for common use, with most of it being used for green areas and equipment. The facilities in the metropolitan experiences of Neighbourhood Units are integrated into the complex, either through dedicated buildings or by occupying the first floors of residential buildings for this purpose.

The common space of the large Neighbourhood Units of the second post-war period is a co-owned space, managed by the communities of new neighbours that inhabit them.

The shared identity is a social capital that in some cases has given rise to community projects, such as the publication in 1966 in the case of the Portales Neighbourhood Unit of the local newspaper Quiubo Vecino.[1]

This local newspaper, produced in 1966 by one of the inhabitants of the complex, can be considered testimony of the new social dynamics that involved the residents of the Unidad Vecinal Portales, built in Santiago de Chile. In this newspaper, products and services were advertised for the neighbours, the residents were invited to participate in community life, and protests were made against the lack of solidarity with the neighbours. **(Fig. 1)** A very representative example of this is the editorial of the Director included in issue Nº. 2 of the newspaper dated July 25, 1966, which describes the objective of this instrument of community building:

Quiubo Vecino! It reached every home in the neighbourhood. It came to make itself known, to show itself. Most of the neighbours welcomed the newspaper with sympathy and enthusiasm. But there were also selfish, indifferent, pessimistic people: they closed their doors, said this was nonsense, that it would fail, etc. It's sad, but there are always people like that.[2]

The article uses an ironic and provocative tone with the objective of denouncing the lack of interest and calling for greater participation from the inhabitants. The same inhabitants who had to live together in this new complex. These neighbours came from different sectors of the city of Santiago, but they shared the lowest common denominator upon which to build the new community. They were all members of the same social security fund and belonged to the same socioeconomic status.

In the case of Brazil, the transformation process took place in the 1960s, when the housing complexes were no longer under the direct administration of the State, which was essential in shaping the broader ideological project of Brazilian workers. The houses built during the Estado Novo regime transcended the sense of a mere "roof over one's head" – they were also aimed at conforming and educating workers. Management of the units went beyond the bureaucratic or physical aspects but stemmed from such convictions and was often closely connected with social work programmes, in which social workers played an active role.

Especially in the housing complexes of the Retirement and Pension Institute of Industrial Workers (IAPI), social workers played an active and direct role in numerous aspects of private and public life. They provided training in home management and child-rearing skills, and organising social functions such as parties and recreation. Such activities were overseen by complex administrators, and are remembered by their residents.

The sale of the residential units marked the end of the social project. Following the sale, the residents themselves began managing the buildings, but only the residential blocks, and the complexes lost their purpose as a

neighbourhood unit that offered several services, such as a school, daycare, health clinic and social club. Residents had to organise themselves into condominiums, whose structure determined whether the blocks would be split or joined, according to the ability of residents to form associations. At the Santa Cruz Housing Complex, in São Paulo, built by the IAPB, residents with a rich history of union organising managed to create a condominium for all the blocks, ensuring their unity. With this, the blocks were not isolated from each other and were fenced off as a unit, not individually. Other complexes were not as fortunate, with condominiums being created for each block, resulting in buildings being fenced off individually, and in the progressive privatisation of semi-public spaces, such as gardens and squares.

Ownership of the dwellings and the properties they are situated on is at the centre of most management and conservation issues for these complexes. Transfer of management to residents led to conflicts that were resolved on a case-by-case basis and according to the capacity of each group of residents to articulate their demands. Residents are responsible for tasks such as trash disposal, collecting maintenance fees, installing new equipment, and solving everyday problems. Pressured by the increasingly common problems of urban violence, the residents of the housing complexes, built on ample spaces open to the streets, began feeling more vulnerable, prompting calls for security measures. However, they often cannot carry out or afford improvements such as installing fencing around the entire plots, which are usually very large and controlled by the public authorities. Actions against urban violence were implemented on a block-by-block, and unit-by-unit basis. Initiatives such as fencing off buildings individually interfere and go against the principles of the modern courtyard by breaking up the building-lot relationship. They go beyond individual attempts to transform and improve homes, such as replacing window frames, a classic management issue in sites of historic interest.

In many cases, the complexes were not built under the most favourable of conditions, and the original projects were far from being completed. Due to construction costs or their location in the urban landscape, the complementary services were deprioritised or not even designed. Often, only the residential buildings were built. In São Paulo, for example, the Várzea do Carmo Residential Complex, by Attílio Corrêa Lima, was only built partially, with nothing more than the residential buildings being erected. The intricate project featuring community facilities such as a school, day care centre, health centre, movie theatre, restaurant, and open areas for leisure and sports never came to fruition.

The Pedregulho Residential Complex, an emblematic work of modern Brazilian architecture, was left to fend for itself for several years, and residents faced challenges in maintaining their apartments. **(Fig. 2)** Despite being abandoned by the government and not owning the apartments, Pedregulho residents appropriated the buildings on their own behalf, making many internal renovations and adaptations. In the 2000s, according to data from Helga Santos, around 50% of the residents were from the initial occupation in the 1960s – mostly comprising service and industrial workers,

as well as civil servants. They were mainly from a working class that enjoyed upward mobility during a period of economic stability for the country, with access to consumer goods that are symbols of recent social transformations in Brazil. Since the apartments are owned by the Government of the State of Rio de Janeiro, which never managed their occupation, the units are transferred or sold in contracts between the parties. In this context, residents were faced with a void left by the authorities and the many visits by architects, and there were growing expectations for a restoration project.

In 2015, the restoration works in Block A of Pedregulho were completed, bringing new visibility to the complex. **(Fig. 3)** The project was kickstarted after inadequate public works by the government, which owns the complex, led to a movement to restore the building, which was then identified as a cultural asset. This movement was taken up by architect Alfredo Britto and the Residents Association of the complex, represented by its director, Hamilton Marinho. It meant involving trade associations and public authorities and putting pressure on the owner of the building to contract a project and carry out the necessary works. The restoration, the only of its kind in Latin America for a modern complex posed various challenges to the materiality and habitability of the place, whose residents attribute great significance to the historically constituted space. The iconic intervention in just one of the blocks has put the rest of the modern project on hold, with expectations for the restoration to be expanded to the neighbourhood unit. The open areas and communal buildings, such as schools, a laundry, and a market, are in an advanced state of disrepair.

4. CONCLUSIONS

Housing is a fundamental aspect of cities and the challenges associated with it are often substantial. Some of the continent's housing developments are close to a century old, while others are more than half a century old. Despite their differences, they all share common problems. We refer to the management mechanisms to administer the life of the new neighbourhood communities

and the mechanisms for the maintenance of the urban environments as well as the buildings that compose them. It is essential to recover the "common good" perspective of cultural heritage mentioned by architects when addressing Latin America's heritage challenges. This involves recognising the values of identity and reference that heritage holds for the community.

It is clear that heritage is created in the present, and in light of its issues, the starting point would be to consider the local values and/or significance for residents, without which heritage does not exist. This path, therefore, can only be travelled from the 'users' of cultural items in their broadest sense, including the imagined communities that are interested in, study and produce social housing. If the history of housing in Latin America has a role that oscillates between reference, criticism, and frustration, we propose discussing how it can also mobilise the idea of cultural heritage. While we agree with Roldan that neighbourhood units have been created far from the sociological concepts that gave rise to them, we would like to point out that there are cases in which neighbourhood units have managed to amalgamate very significant experiences of building social identity among residents. It is crucial to build meanings of permanence and safeguarding based on the everyday experiences and perspectives of the residents and inhabitants. ■

ABSTRACT

In the 1940s, the Salvador Residential Complex (CRS) was built by the Industrial Retirement and Pension Institute (IAPI), standing as an important milestone for housing production in the capital of Bahia - Brazil. This article aims to: (i) introduce the connections between the CRS and the EPUCS; (ii) present the proposal for the common areas; (iii) reveal the appropriations and transformations of collective areas. To formulate these reflections, initially a bibliographic and documentary review was carried out on the proposed concepts and the subject of our study; subsequently, we conducted on-site visits to the CRS to survey its current situation; finally, we organized activities and interviews with the residents to gain further understanding. The importance of this research lies in elucidating the dynamics of CRS based on the relationships between the standard model of its housing units and the collective domestic facilities. Furthermore, the research analyzes the alignment of its implementation with the assumptions of modern architecture and urbanism and the transformations of the CRS in the face of the complex relationship between the proposal about living and the multiple dynamics of individuals in space. In general, these analyzes considered the resident´s' actions and thus questioned how much these spaces represent impositions of the modern architecture and urban planning project.

1. INTRODUCTION

Several authors have discussed the importance of housing production for workers for the architecture of the modern movement.[1][2][3][4] Between formal experiments, debates about the minimum house and technical innovations, countless sets were built around the world, and in Salvador (Bahia, Brazil) this was no different. At the beginning of the 20th century, discussions about social housing emerged, based on a modern conception that dialogued with urban disciplines, referring to the ideals proposed by the First International Congresses of Modern Architecture (CIAM). At this time, two events marked this convergence in the city: the 1st Urban Planning Week, in 1935, and the Salvador City Urban Planning Office (EPUCS), where international ideas about modern minimum housing circulated.

At the end of the 1940s, the Salvador Residential Complex (CRS) was built by the Industrial Retirement and Pension Institute (IAPI),[5] being an important milestone for housing production in the capital of Bahia. The project was designed by architect Hélio Uchoa, an IAPI employee and member of the Brazilian CIAM group and had the participation of EPUCS in the initial phase of the proposal. The chosen area was located on the periphery of the city, a mostly rural area, where there was an intention of enhancing industrialization. The initial proposal was that the CRS would be a Residential Sector of the city and would have had, presumably, a higher occupation than what finally occurred.

In this context, the main objectives of this article are: (i) introduce the connections between the CRS and the EPUCS; (ii) present the proposal for common areas, focusing on what was actually executed; (iii) reveal the appropriations and transformations of collective areas, motivated by the needs of the residents and the urban dynamics, discussing their motivations and needs; (iv) analyze the alignment of its implementation and transformations with the assumptions of modern architecture and urbanism.

To accomplish this, the study conducted bibliographical and documentary reviews, on-sites visits and interviews with residents. These efforts contributed to developing a comprehensive tool to characterize the CRS and assess the satisfaction of its residents.

2. THE SALVADOR RESIDENTIAL COMPLEX

2.1 CONNECTIONS BETWEEN CRS AND THE EPUCS

The Salvador City Urban Planning Office (EPUCS) was established in 1942, under the coordination of sanitary engineer Mário Leal Ferreira, with the primary objective of developing a Master Plan for the city of Salvador, that included the housing issue.

EPUCS proposed that the state should acquire or expropriate lands considered suitable for habitation, organize them into parcels and equip them with all necessary infrastructure. EPUCS recommended where these workers' housings should be concentrated, under the justification that certain regions could function as catalysts for social development. These guidelines appear to have influenced the choice regarding the location of

5. The "Instituto de Aposentadoria e Pensões dos Industriários – IAPI", was established in the Getúlio Vargas Government, and had a great entrepreneurial role, using its social security funds in the production of social housing in Brazil.

the proposal of Vila do IAPI, developed by EPUCS, with participation of architect Diógenes Rebouças (Andrade Junior, 2012).[6]

This plan suggested an occupation of the land with residential blocks on pilotis, arranged in parallel formation, with equipments that appeared to be complementary to the housing proposal and for community use, considering that it has characteristics that may refer to the "Neighborhood Unity" design principles. Based on these assumptions, the proposal for Vila do IAPI, preliminarily developed by EPUCS, seems to align with universal proposals of modern architecture.

Although this proposal was not completed, it served as a guideline for one that was built, located in a different parcel in the same region, the Salvador Residencial Complex (CRS).

At the time that CRS was built, during the 1940´s, the area in which it was established was considered a peripherical one, predominantly rural and with lack of urban infrastructure. However, it had some prior popular occupations such as Corta Braço,[7] inhabited by unemployed individuals or those in precarious work situations. Therefore, the proposal for the CRS fits this aim to promote housing, industrialization and modern planning developed by the EPUCS during that time. It's worth mentioning that the EPUCS plan to the area was never fully executed.

2.2 PROPOSAL

The final proposal for the CRS included 264 residential units distributed in five blocks of four stories, elevated on pilotis, with a single typology of two bedrooms. The Minimum Unit consists of a living room, kitchen, toilet and two bedrooms, articulated by a central circulation area, with floor surface area of 34.09m². There is a concern with the compact spatial organization and with the idea of minimum circulation. The connection of the minimum unit with the external circulation is established by small corridors that lead to the stairs with fan-shaped pattern, a situation that does not allow many interactions between neighbors, because it does not include spaces for permanence. They also do not exist on rooftops that were designed with a single slope.

One of the peculiarities of the complex is that the service area was not implanted in the minimum housing unit, but on the ground floor of each of the five blocks, with three different sizes. In each of these blocks there were laundry rooms equipped with eight concrete washing tanks. This arrangement allowed for the provision of one of these facilities per apartment. These were designed next to the stairwells which, together with the pilotis, were the only elements built on the ground floor. The laundry rooms had some curves and diagonal walls and were arranged to provide certain privacy to the housework. There was no architectural solution to lay the laundry. There weren't other common facilities included in the proposal of the residential complex that was built.

The parallel arrangement of the five blocks on pilotis, with a certain asymmetry, created a collective area for the residents. Initially, this area didn't seem to have any designated purpose for either the residents or the

6. Nivaldo Andrade Junior, *"Arquitetura moderna na Bahia, 1947-1951: uma história a contrapelo"*. Salvador, (Phd diss., PPGAU-UFBA, 2012).

7. The first collective occupation of Salvador (1946).

surrounding community. Rather, it consisted of a large free area that was enhanced by the existence of elevated buildings on pilotis **(Fig.1)**.

The complex, originally open to the city in its design, lacked provisions for community engagement in the sense of being public and serving the broader society. The facilities provided were primarily aimed at serving the residents of CRS, thus moving away from a more substantial implementation of the "neighborhood unit" concept.

As mentioned before, although the CRS was created in conjunction with EPUCS, its ideals were not fully implemented. Nevertheless, the CRS served as a starting point for transforming its surroundings, with a realization that consciously contrasts - and challenges - the pre-existing context.

2.3 CONTEMPORARY APPROPRIATIONS

The appropriations made by the residents of CRS can be understood as an act of making it one's own, demonstrating how these residential spaces were assimilated or rejected by CRS residents, based on their needs, desires, or cultural reasons. Thus, some interventions and their main motivations, which altered elements of the original CRS proposal, will be presented.

Regarding communal spaces, initially, each unit had the right to use a sink located in communal laundries situated on the ground floors of each block. However, this solution was not continued, since residents began to carry out this activity within their own homes, as indicated earlier. Thus, these spaces were vacated, with their sinks removed. They came to be used as storage rooms, changing their physical characteristics from partially open to fully enclosed, becoming underutilized with inappropriate uses.

This situation highlights questions about the adherence of the equipment to the paradigms of modernity, which preached the importance of collective systems focused on domestic tasks as a socialization tool for what would presumably become modern families. The current state of the laundry room reflects a symbolic narrative that encapsulates the tension between collective and private interests. Initially, the space was characterized by its openness, inviting residents to interact freely, and fostering a sense of communal connection. However, its transformation into a confined area with restricted access signals a shift towards prioritizing individual privacy over communal engagement.

Initially, all CRS blocks had open floor plans, with the presence of pilotis, providing free access. However, this space also underwent transformations which were coordinated and executed by the condominium management with the consent of the residents. This led to the assertion of the independence of each block instead of the common relationship established among all of them.

The closure of the pilotis areas resulted in the creation of some access "halls", a feature commonly found in residential condominiums later built in Salvador. The partial closure of some of these areas allowed us to witness fragments of the original solution of the pilotis, the volumes that protect the staircases, and the laundry rooms.

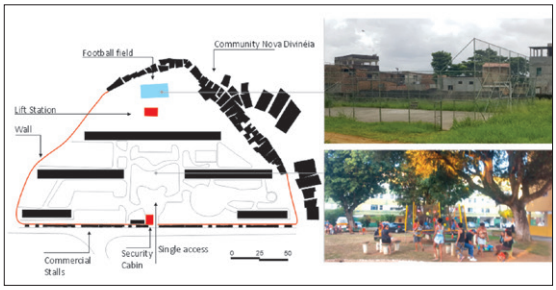

Figure 1 - Implementation of the set and what was really executed. Aerial photograghy. Apartment, laundry and block design. ©Fundação Mário Leal Ferreira; Prepared by the authors, based on Nunes Junior (2020).

Figure 2: Set of images and plans illustrating the transformations. Aerial photography of CRS. Contemporary situation. ©Google maps; Prepared by the authors, based on Nunes Junior (2020).

Figure 3: Set of images and plans illustrating the current situation and the use of collective spaces. Photography and design © Nunes Junior. Prepared by the authors, based on Nunes Junior (2020).

This modification restricted the "Corbusian" principle of free circulation under the built blocks and its permeability relationship in the collective area of the complex. The discourse of modernity intended by the aim of elevating the buildings, and making their ground floors as free as possible, was broken by the possible need to singularize each primary block, making them more easily recognizable compared to the homogeneity of the initial proposal.

The variety of colors of the blocks today also highlight their differences, making identification easier. A different solution from the white and gray color presented on the originally facades, which, in line with what was stated by Kopp (1990) when referring to the monotony of German complexes, could be read as an expression of parity for those who would lived there, "everyone has the same rights and this equality is expressed visually through uniformity and repetition."[8] **(Fig.2)**

Currently, CRS is configured as a closed complex, limited partly by a wall and partly by the community of Rocinha.[9] Despite its recent designation, CRS traces its origins back to an older nucleus that coexisted with the development of this occupation. At the same time, the remaining area of the complex was filled by the above-mentioned occupation, making it a "boundary wall" between these two realities.

The wall in question was built because of the condominium's initiative during the 1990s. However, at the time, residents seemed to lack consensus on the decision. Such an approach stands in contrast to modern architectural principles, according to which buildings should be free from elements such as traditional walls, which would constitute obstacles to surveillance and free movement around the city (Corbusier and Jeanneret, 1929 apud Aymonino 1973). This wall can represent the collective strength

8. Anatole Kopp, *Quando o moderno não era um estilo e sim uma causa*, (São Paulo: Nobel, 1990), 51.

9. Informal occupation bordering the CRS.

in the face of the disorderly growth of the city around it, and with this argument it would make the implementation of walls to protect communal space almost inevitable.

The condition as a closed complex within the city, possibly due to the reasons explained, protected the generous internal space. It is worth noting that, in a similar way, this solution began to be adopted in residential condominiums, especially those inhabited by the middle class of Salvador.

The communal area has come to be recognized as a safe space for residents' leisure activities. These activities include a meeting place for residents, children's play, sports activities, as well as the construction of a general events space in the complex, where parties and celebrations organized by the residents are held, and a gathering and conversation area for residents in the more wooded sections.

The back of the complex is characterized as a sparsely used area, aside from a football field. In this space, there is a sanitation pumping station that is protected by a building and a considerable area bordering the Divinéia community. The frequent use of this space as a parking lot for trucks was also noted.

During the interviews, it became clear that the collective areas became a safe place for residents' leisure activities, gatherings, children's games and sports. These areas were identified as the most valued by the residents, providing a sense of security and allowing collective coexistence practices "under control" and surveillance **(Fig.3)**.

3. CONCLUSIONS

Regarding contemporary appropriations, the analysis of the use of collective areas of CRS revealed that certain functions initially planned for these spaces have influenced the habits of current occupants and others were transformed. This suggests that certain aspects of the original design may have sparked a new way of living from the very beginning of occupancy, a new logic of living that still resonates today.

In some of the collective areas of the CRS, such as the leisure areas, there were no need for significant adjustments and showed positive indications of residents' satisfaction. Nevertheless, changes in uses and transformations were noticed in other collective areas, to meet the needs of current residents, expressing more cultural and economic aspects, such as the collective laundry areas. These changes also emphasized more private customizations at the expense of more collective ones.

The "personalization" of collective spaces sought to meet contemporary demands, based on the pacts established there. The porosity of the complex in relation to the space that surrounds it decreased at the same time as they became increasingly densely occupied, raising the need for control of who and how could access the complex.

The research holds importance in its exploration of the CRS, focusing on the relationships between the standard model of its housing units, linked with the use of the collective domestic equipment and their implementation

connected with the assumptions of modern architecture and urbanism. Moreover, it investigates the transformations of the CRS in the face of the complex relationship between its proposal about living, and the multiple dynamics of individuals in this spatiality. Overall, these analyzes provided insights on the resident´s actions, and thus raised questions about how much these spaces represent impositions of the modern architecture and urban planning project. ■

JUST PATIOS MAKE CITIES? A REVIEW OF THE TOWN PLANNING ASSOCIATES PROJECT IN MARACAIBO, VENEZUELA

ANDREA CASTRO MARCUCCI
UNIVERSIDAD ORT URUGUAY

DANIEL BELANDRIA GUTIÉRREZ
UNIVERSIDAD DE MONTEVIDEO

ABSTRACT

In 1951, Town Planning Associates (TPA) collaborated with the Venezuelan office, Planificación y Vivienda, featuring Architects Moisés Benacerraf, Carlos Guinand Baldó, as well as Engineer Francisco Carrillo Batalla, for a project in Maracaibo. This city was rapidly evolving into a hub for Venezuela's burgeoning oil industry. La Pomona Housing emerged as the only neighbourhood unit entirely conceived and constructed by TPA. The project encompassed single-family homes with central patios, multifamily dwellings, a school, health facilities, a shopping centre, and sports fields. In this endeavour, the architects strategically utilised the patio as a unifying element, responding to the climatic nuances of the region and drawing inspiration from the organisational structure of traditional Venezuelan colonial residences. Despite careful consideration of climatic conditions and cultural context, the complex has undergone substantial transformations, retaining only fragments of its original architectural integrity. This analysis delves into the potential factors contributing to this evolution, centring around three fundamental questions: Was the project designed for Venezuela's demographic landscape circa 1950? Why was the patio-centric housing unit strategy deemed a response to the housing deficit? Furthermore, considering this project as a response to post-war European city reconstruction, why was this model regarded as relevant for consolidating new peripheral areas in Venezuela?

1. INTRODUCTION

As we have seen (…), design objects constantly transform depending on the ways in which they are appropriated, received, and re-signified in each case. Therefore, neither materials, things, spaces, places, bodies, nor architectures can be considered immutable elements whose behavior can be taken for granted and, therefore, anticipated[1]

Town Planning Associates (TPA) was a project office founded by Josep Lluis Sert, Paul Lester Wiener, and Paul Schulz, based in New York and active from 1942 to 1959.[2] Their proposals focused primarily on urban planning, and particularly, expanding Latin American cities. They combined a territorial organisation approach inherited from the International Congresses of Modern Architecture (CIAM) implementing local components from the places they designed for.[3]

During the period from 1949 and 1952, TPA undertook four projects in Venezuela, including two proposals for new cities,[4] one neighbourhood unit, and a single-family house. These projects coincided with the expansion of Venezuelan cities during decades marked by economic growth from oil and metallurgic exploitation, and the establishment of American companies like the Creole Petroleum Company and Chevron in the country.

The growth of urban areas in line with oil and metallurgic activities led to the construction of housing complexes financed by public institutions like Banco Obrero. Most of these projects were designed through the Taller de Arquitectura del Banco Obrero (TABO), in collaboration with other national offices. The TABO's activity has been extensively documented in prior research by Beatriz Mesa Suniaga[5] and Lorenzo González Casas.[6]

TPA arrived in Venezuela as collaborators of the studio Planificación y Vivienda, led by Francisco Carrillo Batalla, Carlos Guinand Baldó, and Moisés Benacerraf. Additionally, Sert had previously been invited as an advisor for the Caracas Regulatory Plan due to his presidency of CIAM and collaboration with Le Corbusier on the Master Plan for Bogotá. Thus, Venezuela became the fourth Latin American country to receive projects from TPA.

2. TPA AND ITS CONNECTION WITH THE U.S. DEPARTMENT OF STATE

TPA's association with Latin America began during World War II. Paul Lester Wiener's wife was the daughter of Henry Morgenthau, the Secretary of the Treasury during the Roosevelt administration.[7] In 1942, the office proposed a prototype series of housing developments for the War Department known as Ratio Structures.[8]

Starting in 1944, they initiated a series of planning projects for new cities in Latin America, including plans for Brazil (Cidade dos Motores), Peru (Chimbote and Lima), Colombia (Bogotá and Medellín), Venezuela (Ciudad Piar, Puerto Ordaz, and Pomona), and Cuba (Havana) **(Fig. 1)**. However, the choice of these cities was not arbitrary; rather, these locations

aligned with the Airport Development Programme established in 1941 between the U.S. Department of State and the War Department.[9]

The primary goal of this programme was to secure strategic locations for raw material extraction needed for wartime production. In the case of Venezuela, eight landplanes were constructed for air communication, operated by Pan American Airlines, along with maritime routes connecting cities along the Orinoco River for the transportation of mineral resources. Consequently, under the guise of commercial activities, a close connection and flow of mineral and oil resources from Venezuela to the United States were established[11].

3. THE POMONA HOUSING COMPLEX

Of all the projects undertaken by TPA in Venezuela, Pomona stands out as the only Housing Development completed in full. Remarkably, this project was also the sole extensive endeavour completed during Sert's entire career. Financing for the Pomona project came from Banco Obrero, which supported most of the housing developments in the country until 1958.

The Pomona Housing Development, located in Maracaibo, Zulia state, was situated in an area that served as the epicentre of petroleum activity throughout the 20th century (**Fig. 2**). The project began during the Military Government led by Carlos Delgado Chalbaud and reached completion under the dictatorship of Marcos Pérez Jiménez. Despite the political turbulence and governance challenges in the country, construction of housing plans proceeded without interruption, as these developments were considered vital for sustaining economic growth.

According to the 1950 census, Zulia experienced exponential growth in its urban population, surging from 61.5% to 75.3%[13] within a period of 9 years due to the expansion of the oil industry. Maracaibo and Bolívar districts served as the primary destinations for this influx of population.

The studio Planificación y Vivienda, under the leadership of Francisco Carrillo Batalla in partnership with Carlos Guinard and Moisés Benacerraf, was tasked with designing the Pomona project and initially engaged TPA as consultants, who later assumed primary responsibility for development. The development was completed in 1951, with construction commencing immediately alongside the planning for new developments in Ciudad Piar and Puerto Ordaz.

The Pomona Housing Development programme encompassed 192 single-family houses, 114 apartments in low-rise blocks, a primary school, a nursery, areas for children's play, a service station, parking facilities, and commercial spaces. The houses were designed in two types: single-family units with yards and apartment blocks. Apartments were categorised into three types based on the presence of terraces and patios, while single-family homes varied across six types with sizes ranging from 74.5 to 94.6 square metres.

Given Maracaibo's extreme climatic conditions, the local office made specific design requirements. Buildings were oriented and shaded to facilitate cross-ventilation within the homes year-round. Extensive

13. (Venezuela, 1950).

eaves and roof covers were incorporated to provide shade over common areas and facades. Additionally, concrete ventilation blocks were used to promote continuous airflow within the buildings. The interior layouts of both single-family homes and apartments were kept straightforward to accommodate the diverse lifestyles of the population.

4. PATIO AS A STRUCTURE

In the Athens Charter (1933), Le Corbusier divided the city's organisation into four fundamental zones based on its function: living, working, recreation, and circulation[14]. Building on this, Josep Lluis Sert, following his collaboration with the Swiss-French architect and as president of CIAM (International Congresses of Modern Architecture), introduced the *patio* as a fifth function, enriching the functional framework of new cities.

The patio, serving as an organising element, evoked the social activity seen in ancient public squares. By scaling urban design to a pedestrian level, the patio facilitated interaction among inhabitants, nature, and recreational spaces. Sert also envisioned the patio as a democratic element where all citizens were equal, advocating for its inclusion across all aspects of city planning.

TPA's urban proposals served as a way of experimenting with different uses of the patio. In their 1953 article "Can patios make cities?"[15] published in *Architectural Forum*, Sert and Wiener described the diverse architectural solutions achieved through patios in Latin American cities: from patio houses and neighbourhood patios to patio parks, buildings, and civic centres **(Fig. 3)**.

The Pomona Housing Unit exemplifies this use of the patio concept. The patio is integrated as a key functional element within each of its designed spaces. Referring to the aforementioned article, we can identify the following types of patios at Pomona **(Fig. 4)**:

Patio houses: Two types are present in single-family units: interior patios that connect different spaces within the house, and rear patios that provide a connection to the exterior.

Neighbourhood patio: Located on the ground floors of residential buildings and within apartment complexes, often featuring terraces and balconies.

Patio buildings: Notably integrated into the school at Pomona, where classrooms are raised on stilts over a continuous patio extending into play areas.

Civic Centre Patio: Although Pomona lacked a formal civic centre, the commercial hub was organised around a central patio, shaping the surrounding commercial areas.

5. THE POMONA HOUSING COMPLEX, 70 YEARS LATER

Despite the considerations made by the studio Planificación y Vivienda and TPA, the Pomona Housing Complex experienced successive alterations to adapt to the lifestyles of its inhabitants. Today, few traces remain that allow for the identification of the original project. The concrete ventilation blocks on the facades were filled in to enhance home security and install

mechanical ventilation equipment while living areas were extended to occupy the entire patios.

Exploring aspects that may have been overlooked by the architectural teams, two factors stand out: the development of housing projects in response to housing shortages, and the consolidation of Maracaibo's peripheral areas.

One relevant question to consider today concerns the relevance of the Neighbourhood Unit model for Latin American cities. In the specific case of Venezuelan cities, there was no general city planning to connect these neighbourhood units, resulting in isolated populations to which, in subsequent decades, vast extensions of informal settlements developed, attracted by the provision of basic services such as water, electricity, waste collection, among others.

The truth is that as they were state-promoted developments, it was unaffordable to develop many other neighbourhood units like Pomona. However, during the same period, the General Rafael Urdaneta Urbanisation was also constructed, designed by the Venezuelan architect Carlos Raúl Villanueva. Subsequently, other multifamily building complexes like Las Pirámides were built, further consolidating the area as a residential zone where planned developments coexist with informal housing.

6. FINAL REFLECTIONS

The Pomona case appears to demonstrate that architectural ideas or intentions alone are not enough to achieve successful outcomes. The inclusion of multi-scalar patios, intended to complement the ideas of the CIAM, aimed to provide a spatial connection between communities and thus ensure the long-term viability of this type of urbanism. However, the uncontrolled growth of Maracaibo City and various unexpected situations hindered the success of the original plan.

These situations vary in nature; nonetheless, they all have a political origin with significant institutional and social implications. A number of relevant issues can be highlighted from this:

The interconnection between these types of housing complexes and urban centres must be carefully planned from the outset and reinforced over time. Viewing these interventions as anchor points that the city relies on to expand seems to be the correct strategy. Otherwise, they are doomed to become inert islands within an urban landscape that develops independently and according to its own rules. However, such situations are beyond the control of the architectural project and depend on a level of planning at the metropolitan scale, which, in this case, was nonexistent and beyond the architect's scope.

6.1 THE GOVERNANCE OF MODERN GROUND FLOORS

Like many modern housing complexes, the Pomona Housing Unit featured open ground floors designed to facilitate interconnection between buildings. Nevertheless, there were no clear guidelines for managing these common areas. While their creation was a significant achievement for Latin American cities, the lack of administrative capacity or tradition resulted in liminal spaces that quickly deteriorated.

16. Own elaboration. Image © Wiener, P. and Sert, J. "Can Patios Make Cities?" 1953.

Organisational weaknesses—whether public or private, institutional or collective—led to the emergence of vacant spaces that were swiftly occupied by the homeless. This occupation, initially temporary, eventually became permanent, resulting in entire communities inhabiting informal spaces linked to the original urban project, significantly altering it.

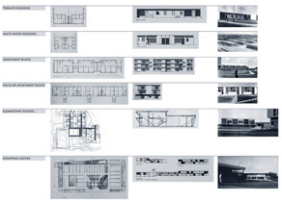

Figure 4. Patio typologies in Pomona. Author's elaboration based on the Pomona Neighbourhood Unit plans. (Villanueva, C and Celis, C., 1953).

6.2 MULTISCALAR VANDALISM

The vandalism of the urban project to obtain basic services is another immediate consequence of the informalisation. A curious fact, in many Latin American cities, informal settlements disrupt planned urban developments by illegally obtaining services. Faced with the government's inability to control and respond to informal occupation, these new communities meet their energy and waste needs through pre-existing installations, exceeding their capacity and causing them to collapse. All of this occurs without any legal consequences.

As a result, the complex underwent various interventions to include peripheral fencing throughout the sector, aimed at controlling access to common areas. This pattern is repeated on a smaller scale: the front and back yards of single-family homes were fenced in and, in many cases, incorporated into the interior of the home.

Vandalism is not, however, limited to services and common areas. Smaller open areas, initially intended as private courtyards, end up providing opportunities for theft by newly emerged criminal elements. Consequently, this architecture designed for well-being and community living is voluntarily altered by the occupants to mitigate insecurity.

Fig. 5. Original (1952) and current situation. Own elaboration. Image (left) from Villanueva, C and Celis, C., 1953.

6.3 FINALLY, THE MARACAIBO METRO

In 2008, another large-scale public intervention, such as the consolidation of Sabaneta Avenue and the construction of Line 1 of the Maracaibo Metro, ended up isolating the sector from the urban fabric. Thus, urban evolution along with socio-political conditions have reduced or nullified the initial project's ability to provide the planned quality of life for its inhabitants, making it seem even flawed or useless in terms of its original purpose.

Anticipating and avoiding such unforeseen situations depends on metropolitan-level planning that exceeds the scale of the urban housing and facilities project. Moreover, integrating these large-scale projects within an urban development plan surpasses architectural vision. Creating the right conditions for the success of such interventions is in the hands of the local administration. Effective institutional performance, on which urban planning directly depends, is possible only in a political context that offers favourable conditions: democracy, transparency, and administrative continuity.

Good projects rarely thrive under bad governments. Over the years, informality has created an amalgam that reaches and erodes this type of urbanism. In Pomona, the original sound design was unable to adapt to the numerous unforeseen and negative changes, preventing it from flourishing as the intended haven of well-being. ■

THE EMPART I HOUSING COMPLEX IN IQUIQUE, CHILE. COLLECTIVE HOUSING IN A DESERT LANDSCAPE

VÍCTOR VALENZUELA-GROLLMUS
UNIVERSIDAD ARTURO PRAT. IQUIQUE

#14

ABSTRACT.

The present work forms part of a doctoral thesis focused on the study of housing estates constructed between 1936 and 1976, situated in four port cities of northern Chile: Arica, Iquique, Tocopilla, and Antofagasta.

Using the Empart I housing estate, constructed by the Caja de Empleados Particulares (1963-1965) and designed by architects Alberto Sartori, Francisco Schlotfeldt, Jaime Silva, and Sergio Arias, located in Iquique, as a case study, this research aims to uncover its history and the design strategy devised by its creators through planimetric analysis, periodical publications, local press, and relevant literature on the subject.

The investigation of this housing estate has allowed for an understanding of the influence of modern architecture on an intermediate, remote, vibrant city, located on the border, which was one of the latest to be incorporated into the national territory. Furthermore, it has emerged as a noteworthy local case in terms of enhancing housing conditions in the Norte Grande and fostering community life by establishing a new urban landscape.

As part of this study's findings, it is evident that this housing project demonstrated the adaptation of modern movement ideas, manifested in both its architectural design and its location, to address the conditions of the desert landscape and an urban context with heritage significance, proposing an adaptable and resilient architecture in response to the environmental conditions of the desert.

1. INTRODUCTION

Modern architecture developed in northern Chile, specifically in the four port cities of Arica, Iquique, Tocopilla, and Antofagasta, proved to be particularly suited to these newly annexed territories, which became a laboratory for architectural and urban experimentation. The designers were able to address the particularities of the desert, and through these new architectures, which "dialogued with the specificities of each place under a modern language, increased the sense of belonging and identity of the progressive northern society throughout the 20th century."[1]

The scarce precipitation, moderate temperatures indicating a good climate, combined with the geographical features, colours, and contrasts, turned the coastal desert into a unique and attractive environment for architectural experimentation and the development of housing complexes. These complexes enabled people to settle in these distant cities, leading to their growth and development.

Upon review of disciplinary sources, photographic records, and conducting field visits, it is evident that the housing complexes were a tangible realisation of ideas, visions, and institutional policies coloured by the experience of a modernity shaped by an extreme landscape. Examples include the Collective Buildings (1942) constructed by the Caja de Seguro Obrero Obligatorio in the four aforementioned cities, the Chinchorro (1955) and Estadio (1957) housing developments managed by Sociedad Modernizadora in Arica, as well as the Gran Vía Housing Complex (1955-1976) constructed by the Caja de Empleados Particulares (EMPART) and the Salar del Carmen Housing (1964), developed under the Housing Corporation (CORVI), both of which are located in Antofagasta. These are representative works of the Norte Grande and have become part of Chilean and Latin American architectural historiography.

However, in all these cities, smaller-scale housing complexes were also built, which managed to consolidate the urban block both in central and peripheral areas, and created new ways of making a city. In Iquique, particular attention should be paid to the Empart I housing complex or "Población Cachimbo," for the Caja de Empleados Particulares, designed by architects Alberto Sartori, Francisco Schlotfeldt, Jaime Silva, and Sergio Arias.

This residential project was featured in the Chile Housing Plan (1963), a publication by CORVI. It presents the work of the institution through a selection of cases representing its activities across the country. The residential complex, based on the combination of low-rise blocks and housing, is showcased through images that express a distinctive architectural language interpreting and responding to the climatic conditions of the desert's aridity.

To highlight the most relevant aspects of this residential project, the following sections will address the circumstances and background that facilitate its understanding and particularly its significance as part of the housing laboratory conducted in Northern Chile.

2. HISTORICAL BACKGROUND OF THE COMPLEX

The genesis of this housing project dates back to January 25, 1963, when CORVI issued a public call for the construction of a housing complex for

1. Claudio Galeno. "Confined Laboratory: Modern Architecture in Northern Chile." *Revista de Arquitectura* 14, no. 17 (2008): 18–29.

members of the Caja de Empleados Particulares. According to local press reports, the complex was to consist of "18 two-storey houses and another 24 apartments in four-storey blocks."[2] The construction of this new housing project commenced in June of the same year, at a cost of 650 million pesos.[3]

Local press followed the housing developments in the city closely, considering the gradually increasing demand for housing as well as the changes and improvements introduced by such projects. They noted the following:

> *"Iquique, which for years was characterised by its lightweight buildings, reminiscent of the old American west cities, and still having some wooden structures in certain areas, is now seeing the rise of modern and earthquake-resistant constructions made of concrete and steel. Numerous banking institutions, as well as industries and traders, are currently modernising their buildings with these materials, with many also demolishing their old structures to erect modern buildings. CORVI, for its part, has already begun the construction of more than 150 solid-material houses as part of an organised programme started last year. All these works, in addition to creating new job opportunities, are enabling Iquique to advance rapidly in its urban development."*[4]

The construction of this housing complex thus became a valuable contribution to the renewal and densification of the city's central area, as well as part of the solution to the housing demand and improving living conditions in a desert city. The formal expression of the project did not go unnoticed by the local press. Photographs from the construction process highlighted that: "The housing complex being built by the Housing Corporation between Aníbal Pinto and O'Higgins streets will have a unique architectural style. This housing block will feature 42 houses of two or more storeys,[5] which will beautify the area." This indicated morphological similarities to the houses in the Población Salar del Carmen in Antofagasta, which had an aesthetic reminiscent of houses in North Africa, reflecting similar climatic conditions to those of Northern Chile.[6]

Finally, on February 13, 1965, the Caja de Previsión de Empleados Particulares handed over the houses and apartments of the housing complex, which "not only beautifies our city but also alleviates the acute housing problem faced by Iquique, caused by the industrial progress experienced,"[7] as reported by the local press. The keys were handed over to the selected occupants in the presence of authorities, and a tour of the new neighbourhood was subsequently conducted.

3. THE URBAN-ARCHITECTURAL PROPOSAL AND ITS SCOPE

This housing complex was situated on land belonging to the Diocese of Iquique, on one of the largest urban blocks in the area, close to the historic centre of the city. The lot, which had an area of 5,129 m^2, had an L-shaped configuration that allowed for two frontages.

From a regulatory perspective, the land was located between two zoning areas according to the Iquique master plan of 1960: the Historical Conservation

Residential Zone, with a maximum height of two storeys, and the Residential Zone Type One, South Port sector, which permitted a maximum height of four storeys. This dual condition explains why the existing façade lines are set back, as a strategy for placement and to respect the building line in the area of the block that was under mixed urban conditions.

The general layout is based on the arrangement of five residential blocks, four of which are situated on the eastern frontage (blocks A, B, C, and D) facing Aníbal Pinto Street, which has an urban character and runs north-south through the historic centre of the city. Two blocks provide the main access to the complex, which is topped by an open space in the centre of the roof slab that connects them, and also houses the staircase leading to the aerial corridor of the complex.

At the ends of the facade are the other two staggered blocks that complete the eastern frontage. Additionally, there are areas designated for parking, service cabinets, and access to the ground-floor apartments. The fifth block (E) is positioned parallel to the interior of the complex.

The eighteen houses that make up the complex are located in the interior, making up both the perimeter of the central communal space and the irregular edge of the site, which is managed through the patio of each unit. The two-storey houses are primarily arranged in pairs, but with some modifications, such as the connection between units via an open terrace on the second floor or the party wall when there is a stagger between the houses.

Daily life would occur within the housing complex, which did not allow for automobile access, placing further emphasis on domestic scale, social cohesion, and neighbourhood life for its residents. This concept remains a unique residential space in the city to this day.

Regarding the characteristics of the units, the housing project proposed five blocks with the following units: four ground-floor apartments of 59 m^2 and twenty duplex apartments of 74 m^2, and eighteen single-family homes, each with 70 m^2 of built area, including a private yard and front garden. All residential units included three bedrooms and one bathroom.

The impact of this housing complex within the residential production developed by CORVI is also acknowledged by scholars in the field. For example, Raposo (1999) cites it as a case study to highlight the housing developed by this institution as architectural and urban heritage, noting that:

> *"At the microsystem level, these are building types and grouping morphologies that architecturally express a concept of residential community, family, and domestic lifestyle, organisation of coexistence, conditions for the reproduction of social life, and the socialisation of individuals in habitability."*[8]

This description highlights the process of consolidation and housing experimentation occurring in the country, with Iquique presenting itself as the only complex capable of providing a new kind of urban interiority, in addition to offering privacy for its residents' daily activities.

By comparing the residential strategies developed in Israel, which share similar climatic conditions, it is evident that in order to consolidate middle-

8. Alejandro Raposo. "The Social Housing of CORVI: Another Heritage." *Revista INVI* 14, no. 37 (1999): 41–73.

class housing, as seen in the EMPART complex, efforts were made to articulate "the individual and the collective, the private and the public."[9] These actions allowed for the creation of a community identity in housing complexes within a desert environment by integrating different spatial scales through balconies, walkways, and front gardens.

4. FROM HOUSING COMPLEX TO SOCIAL CONDOMINIUM

The EMPART housing complex was a modest-scale residential project in which its designers effectively considered the urban, social, environmental, and territorial conditions of the area. Moreover, this case highlighted the role of housing in Iquique as a political tool for social progress, demonstrating that the construction and development of housing complexes, even on a small scale, positively impacted on the local community by fostering well-being, community roots, and resilience in the face of the challenging conditions of the territory.

Some of the latest adversities faced were the earthquakes that occurred on April 1 and 2, 2014, with magnitudes of 8.2 MW and 7.7 MW, respectively, affecting the main cities of Northern Chile. Among the infrastructures that were affected were social housing complexes in Iquique. Although the EMPART complex did not suffer from major damage, it was included in the list of social condominiums[10] that benefited from repairs and improvements provided by the Ministry of Housing and Urbanism.

These actions were initially carried out in 2016 and involved cleaning and painting the facades of the blocks, repairing cracks, and restoring common areas, particularly sidewalks, to current standards. As a result, the social condominium "Arturo Prat," as it was later named by the community, began to recover and improve its usability. The local authority recognised these efforts, stating:

> *"Social condominiums like 'Arturo Prat' are a jewel of our regional architecture, demonstrating the housing policy developed by the State 50 years ago. Today, we are once again building social housing of this scale that provides a higher quality of life to families opting for subsidised housing solutions."*[11]

These statements demonstrate the benefits of constructing micro-neighbourhoods in Iquique during the 1960s.[12] Although driven by economic reasons, this approach allowed for a limited number of families, which facilitated more effective and direct coordination among neighbours, particularly in decision-making that could involve them, as was evidenced during the repairs in 2016.

Additionally, the involvement of residents, recognition by authorities, and academic contributions, such as the study of the Master Plan since 2018, have elevated local modern architecture as part of the city's heritage and preserved a set of anonymous and ordinary works,[13] like the EMPART complex, which, after over fifty years of use, is now undergoing a new phase of renewal in its communal spaces thanks to collaborative efforts between residents and government[14]. ■

ABSTRACT

In the mid-twentieth century, through the establishment of housing institutions, the Colombian government faced the challenge of providing proper accommodation to urban families in order to alleviate the deficit and improve living conditions. Once the homes were assigned and delivered to the new families, the housing institutions gradually relinquished the responsibility of managing and maintaining properties, transferring the responsibility to the new owners. According to the high-rise co-property regulation Law 182 of 1948, they had to establish community rules to manage and preserve the buildings, facilities, and green open areas.

Centro Urbano Antonio Nariño - CUAN is a neighbourhood unit built in Bogota between 1952 and 1958, which has been remarkably well-preserved. Its significance to the history of modern architecture in Colombia has been widely studied, but little has been said about the implications and challenges of its maintenance. Currently, there are legal regulations that govern the procedures and limitations for physical improvements such as the National Co-ownership Law 675 of 2001, the CUAN co-ownership regulations and the declaration of Cultural Interest Property. Even so, not all modifications are carried out under these instruments, small adjustments have been promoted by neighbours to beautify, singularise and decorate the common spaces.

Based on direct observation and interviews with current residents, this paper intersects the discourses underlying the principles of the neighbourhood unit and the present appropriation of the common spaces at the Centro Urbano Antonio Nariño. Drawing on theories of the production of space and the social construction of taste, the analysis highlights the strategies implemented by small neighbourhood communities to update common areas thus promoting spatial and ornamental adaptations that align with the desires, ideals, tastes, and needs of the inhabitants. The aim is to shed light on non-formal community agreements to unveil the assortment of activities, users, and affections deployed in the common spaces.

1. INTRODUCTION

During the first half of the twentieth century, the unstoppable tide of rural-to-urban migration changed the urban fabric of the main Latin American cities. The accelerated rate of population growth resulted in deplorable residential standards, the mushrooming of informal housing, the construction of "shantytowns" on the outskirts, and overcrowding in old traditional houses. In the book *Cities of Latin America. Houses and planning to the south*[1], Francis Violich pointed out that two-thirds of the population inhabited precarious housing with lacking living conditions.

Colombian peasants who migrated to the large cities were attracted by better living conditions, work, education, and security, which contrasted with the impoverished rural areas affected by a civil war called "La Violencia". Investment, development, and concentration of capital were more than evident in the cities and naturally, internal migration to the principal towns: Bogotá, Cali and Medellin, increased the housing shortage and transformed the urban landscapes. As a result, the Colombian government faced the challenge of providing housing by addressing the deficit and improving living conditions for workers and employees through the creation of institutes and housing programmes throughout the country.

The Ministry of Public Works introduced a national infrastructure plan for the physical transformation of cities with the construction of public buildings that communicated, through architecture, the power and governance of the state. Although the Instituto de Crédito Territorial - ICT, the Banco Central Hipotecario - BCH, the Caja de la Vivienda Militar – CVM and other institutions were in charge of state social housing, the ministry promoted the most important state multi-family housing project: the Centro Urbano Antonio Nariño[2] in Bogotá, designed by the architects Néstor C. Gutiérrez B.[3], Daniel Suárez Hoyos, Rafael Esguerra García, Enrique García Merlano, Alberto Herrera V., Juan Menéndez, Jaime del Corral y Álvaro Cárdenas and the engineers Doménico Parma Marré and Guillermo González Zuleta.

The ICT, responsible for selling the apartments, progressively withdrew the management and maintenance obligations upon awarding and delivering the apartments to the new families. This was done in order to transfer the responsibility to the residents and prepare the community to undertake the complete and independent management of CUAN within a short timeframe. The legislation pertaining to the ownership of apartments in the same building, Law 182 of 1948 "high-rise co-property regulation", required owners to establish the community rules and select an administrator to manage the financial resources for the maintenance and operation of the buildings, facilities, and green open areas.[4]

Historians have emphasised the importance of the CUAN for as the first attempt at multi-family state housing for sale through horizontal ownership. It was based on self-sufficiency and establishing a new communal life under the neighbourhood unit model. The project was built on a plot of land measuring 150.815,93 sq metres, and the construction of the building occupied 16.589,75 sq metres (11% of land use) and included

1. Francis Violich, *Cities of Latin America. Houses and planning to the south*. (New York: Reinhold Publishing, 1944)

2. The civil works began in May 1952 under the supervision of the Ministry. In 1953, when the structure had already been completed, the construction was suspended for a while and the project was sold to the Banco Popular, which modified two buildings to turn them into hotels. In 1957 the Ministry recovered the property and then sold it to the ICT, which was in charge of the sale of the apartments. Finally in 1959, the two blocks transformed into hotel rooms were sold to the Corporación de Residencias Universitarias of the Universidad Nacional de Colombia, to be converted into dormitories.

3. Prior to the design of the project, Gutierrez was sent on a commission to visit and study examples of the most important residential architecture in the continent, in Venezuela, Mexico, different cities in the USA.

4. Victoria Sánchez, *Colombia's History of Modern Architecture revisited through the housing agency Instituto de Crédito Territorial: 1939 - 1965*. Austin: PhD. Dissertation University of Texas, 2018, 304.

134.226 sq meteres[5] of open areas in which there are 960 apartments distributed over nine[6] 13-story towers and six 5-story blocks, long corridors, lifts, staircases, free ground floor-plants, gardens, and different facilities such as schools, market, laundry, church, theatre, playgrounds, sports courts, parking lots, etc. **(Fig. 1)**. Its importance in Colombian architectural history is unquestionable. However, little has been said about the implications and challenges of keeping the project up to date to fit today's lifestyles after more than 60 years of occupation.

Based on the theories of the production of space and the social construction of taste, the analysis highlights the non-formal strategies used by small neighbourhood communities to maintain, preserve, and keep common spaces up-to-date and promote ornamentation plans that reflect the desires, ideals, and needs of today's inhabitants within a modern project.

2. THE CLASH: IDEAL TO REAL

Idealisations are formed by overlapping concepts and representations of what a place can become without directly addressing the problems that such a place should solve. These types of representations are abstractions of a projected future without socio-spatial definition or a certain organisation of space according to reality, as Henri Lefevbre claimed in the *Production of Space*[7]. In architecture, abstractions often prioritize manipulating shapes and forms over actual content, as Fernando Lara described as "the quality of dealing with ideas rather than events, or something that exists only as ideas… plans do not register community life."[8]

The concept of the *neighbourhood unit* served the government and architects to plan major housing projects and to provide housing for large number of families. To this end, the resident selection process was one of the main tools available to the ICT to ensure that the inhabitants of their neighbourhoods met its ideal expectations. Income and family unit size were the criteria of selecting middle class residents to satisfy the income group that the Ministry of Public Works wanted for the project.[9]

This idealisation of the *neighbourhood unit* as the solution to the "housing problem" in Colombian cities clashed with the actual reality of the families occupying the CUAN. On the one hand, the assumption was that through mass housing projects, new residents would be taught how to be modern inhabitants in a changing city, by assuming a single way of life for all families, determined by the mortgage loan payment capacity and the number of inhabitants per unit, while ignoring their cultural backgrounds, habits and needs. On the other hand, the typology of high-rise blocks freed up the common floor, conceived as the ideal space to foster social interaction and support the collective activities of the residents, avoiding the fact that 89% of the ground is an open area that will require permanent maintenance, which becomes an extra expense to be paid by the co-ownership. **(Fig. 2)**.

The circumstances made it difficult for a cohesive and effective community to take charge immediately of the maintenance of its own project. As a result, both the community and ICT were compelled to

9. According to Sánchez, moral standards were set for selection process such as: christian habits, legitimate children and good habits. Sánchez, Victoria. *Colombia's History of Modern Architecture revisited through the housing agency Instituto de Crédito Territorial: 1939 - 1965*. Austin: PhD. Dissertation University of Texas, 2018, 311.

manage the project on a collaborative basis until the end of the 1960s.[10] However, it was not always an easy relationship that certainly reduced the space for residents' participation in administrative decisions. Since then, different legal instruments have regulated the physical improvements made in the CUAN. The current National Co-ownership Law 675 of 2001 grants exclusive property rights over private property and co-ownership rights over the land and common property. The CUAN's co-ownership regulations govern the interaction between community members. Additionally, the property was declared a Cultural Interest Property in 2001, highlighting its architectural and urban values and its importance for Bogota and the country as it inaugurated a new urban way of life.

Despite this, not all the modifications are carried out under these instruments; small adjustments have been promoted by the neighbours to beautify, singularise and decorate the common spaces. Inhabitants have renegotiated the conditions set by modern architecture in the production of space and its appropriation over time, which occurs differently in the project based on the location and its occupants.

3. CONSENSUS: APPROPRIATION AND EVERYDAY LIFE

In an effort not to compromise on the physical or spatial values of the project or the aesthetic principles that emphasise its uniqueness in the architectural context, the taste(s)[11] which have been spatialised in minor physical interventions can now be traced back to its origins and the life stories it harbours.

In the CUAN, there are four different levels of appropriation of the common areas. In general, the residents interviewed expressed their awareness of the importance of the CUAN for the history of architecture. Therefore, the care of the project is assumed as a civic duty because "the CUAN belongs to Bogotanos"[12]. Furthermore, the notion of a highly walkable city, with complementary services and isolation from the surrounding chaos is among the favourable conditions highlighted by residents. Undoubtedly, nature is part of the created landscape: "one of the virtues of the proposal is that the freed-up land is occupied with new concerns, such as the incorporation of the natural environment as part of the programme."[13]

The second level of appropriation is the direct impact of shared amenities such as schools, theatre, supermarket, church, laundry and stores in the surrounding area. Although the CUAN administration oversees general maintenance, individual facilities such as the store, laundry and church manage themselves, while the theatre and schools are overseen by the Secretary of Education and Culture respectively. Such entities make decisions on the immediate physical environment of the buildings: fences, gardens, trees, floors and furniture.

A third level of appropriation can be observed in common areas of the ground floor without the direct influence of a building. These spaces are transformed by neighbourhood communities for collective activities and are open to those who wish to participate. Activities include soccer

(in a local league), urban agriculture, gardening and planting of fruit and aromatic species, recreational activities such as yoga, aerobics or Zumba, gymnastics for seniors, and cultural activities such as story time, literary picnics or carpentry workshops[14].

Finally, a fourth level of appropriation is driven by differentiation between the occupants of each one of the buildings. The six four-story blocks mostly house public residences for the military forces. The one-bedroom apartments are generally rented to young couples or individuals, with only a few owners living there. Families with one or two children at most, or seniors, reside in the larger apartments. Since the 1960s, the fence has isolated the block designed as a hotel, which is managed by the Universidad Nacional de Colombia, with no contact with the residents at the present time. Therefore, the location of the blocks in the project and the "type" of resident, have a direct impact on the intervention of the surrounding spaces and their appropriation.

The buildings under military care have a specific budget and maintenance guide that applies to the surrounding areas. The participation of this community, although active in the general meetings, depends directly on the Instituto de Casas Fiscales del Ejército de Colombia. Homeowners residing in the CUAN are undoubtedly the most active in conducting integration and beautification activities. The administration is responsible for

the maintenance and operation of the common areas in each block: elevators, corridors, premises, stairways, etc., activities enshrined in the horizontal property regulations.

In the blocks where there are more resident owners, it is common to find many minor interventions made to the immediate access areas. This can include the changing of flooring, planting of new trees, installation of ornamental fountains, ground and hanging pots, installation of benches, change of lighting, zoning of bicycle racks, flowers and special gardening features **(Fig. 3)**.

4. CONCLUSION

The users create spatial consensus to overcome formal unity, monotony, rationalisation, and typification, by constructing their own friendly environments for the community.

> *The greatest value of the complex is its common spaces. With 70 years of existence, the balance that can be made from the operation of CUAN is positive. The declaration of "Cultural Interest Property" allowed owners to fund conservation initiatives. The adjustments that have been made in the mechanisms of community life determined by the design of the complex have allowed to overcome periods of crisis, after which the perimeter was closed, and a management plan was drawn up that has given the compound a clean and cared for aspect to the blocks and their common areas.*[15]

The common spaces used on a daily basis are irrefutable proof that reality has surpassed the ideal of modern housing and that the life of the projects has taken the reins in the differentiated and complex occupation of the spaces. Small strategies of spatial intervention have favoured the CUAN and have breathed life into it for more than seven decades of use. This approach allows us to recognise the value of common spaces, not only as an extension of the activities of the home, but also as an opportunity to create community ties that are spatialised in small interventions. Considering the relationship between society and space in projects such as CUAN is an excellent input for identifying, on the one hand, how space is used today and, on the other, to reveal innovative non-formal strategies for conservation, habitability and coexistence over time. ■

14. The contributions for this type of intervention come from: CUAN Community Activities Fund, Voluntary contribution from residents, Development of fundraising activities or Crowdfunding.

ABSTRACT.

Urban planning principles associated with the Functional City revolve around four collective functions: residence, work, recreation, and mobility. In the CIAMs, it was determined that housing discussions should always be associated with solutions that seamlessly integrate each project with the city in terms of its relationship with facilities, services, and circulation.

In the 1970s, Ecuador explored and implemented many modern housing projects based on late Modernism criteria. In the north of the city, high-rise buildings were planned with typology responses and innovative techniques, which were widely disseminated. In contrast, in the south of Quito, low-scale social housing was developed far from the economic poles, as stated in texts from the National Housing Board in Ecuador declaring this phenomenon.

The social housing project "Santa Anita", designed by architects German Samper and Fausto Banderas in 1970, works with the functional parameters of the Quito regulatory plan. It was proposed as an urban island of low-scale housing for workers. However, the project sought to establish a link on an urban scale as it was not designed exclusively as collective housing but rather treated like a block within the city - built as a replicable scheme in an additive spatial logic as part of the urban fabric.

Despite the generic condition of its collective spaces, the presence of transitional areas between housing groups and internal streets balances privacy and communal life.

Santa Anita presents itself as a social housing complex that, from its initial conception, gives primary value to the hierarchical arrangement of the ensemble over the individual housing units. The project operates through a system of layers that articulate the public, the collective, and the private. Through a multiscale approach, the project effectively articulates a balance between the individuality of residential units and the notion of the block ensemble.

1. PROJECT BACKGROUND

Santa Anita complex is located in the southern area of Quito. It was developed during the mayoralty (1970-78) of the architect Sixto Durán-Ballén (1921-2016), who led numerous projects in Quito aimed at giving a Modern character to a town with a strong Colonial and Republican heritage. These projects were justified through the Quito Regulatory Plan from 1945 led by Uruguayan Guillermo Jones Odriozola. The plan was characterised by the sectoral development of Quito from a hygienist and socially fragmented perspective, with the southern zone dedicated to the expansion of working-class neighbourhoods.

In addition to municipal support, the project involved "Mutualista-Pichincha'' as an economic manager. This institution qualified the financing and characterisation of future inhabitants. Santa Anita stood out as an anomaly in the Mutualista's profile since it was a project targeting a low-income population.

The project features a bi-national team from Colombia and Ecuador. Germán Samper, a prolific Colombian architect, led the design team at the age of 46. Samper had a solid discourse about the role of social housing in the context of Latin America. Samper's emphasis on "*low height and high density*" guided his design philosophy, influenced by his studies under Le Corbusier. His notable project "*La Fragua*" in Bogotá earned international recognition, leading to his participation in the PREVI competition (Lima,1967-1969). Fausto Banderas, who was 31 years old at the time, represented Ecuador, and the local team included Henry Carrión in a supporting role.

Fausto Banderas is a prominent architect in the local architecture scene, born in Ecuador but educated at UDELAR, Montevideo. He kept his office open for business until 2020, engaging in a prolific production of collective housing, government buildings, and other uses. His personal brand is often associated with the use of exposed brick, influenced by Eladio Dieste, who was once his professor in Uruguay. This collaboration, unusual for low-income projects, echoes historical architectural episodes in Quito during the mid-20th century under Sixto Durán-Ballén's administration.

2. PROJECT DESCRIPTION

Santa Anita was originally planned to have 80 blocks of 50 houses each, totalling 4,000 units, from which only 200 houses were built in 4 blocks. On each block, there was a communal nucleus consisting of a park centre and parking space on two differentiated platforms. Around this block centre, there was a ring of two-storey houses built on 20-metre-deep lots, forming a square cut at its edges by pedestrian passages connecting to the streets.

These pedestrian passages were covered at their ends by the so-called "bridge-houses", which allowed for flanking the inside of the block, creating an intimate character. The bridge-houses required the establishment of specific regulations that enabled the designation of private property under public space at ground level in such complexes, making this spatial mechanism a novel resource in Quito.

The block created this geometry through the association of four different types of houses, including the bridge-house, that allowed for the creation of a set with diverse options within the limited space available of the lots. The two-storey houses separated the social area on the ground floor from the bedroom area on the upper floor. The facades present a diverse catalogue of formal resources to define the individual geometry of each house through construction joints, as well as a subtle and proportionate interior/exterior relationship, giving an austere character to the complex.

3. URBAN IDEALS

Jones Odriozola's (1942-1945) regulatory plan for Quito proposed a spatial organisation based on rigid zoning, systematically grouping a series of interconnected elements at different scales. He likened it to the human body, where "cells, tissues, and organs united by circulatory, nervous, and skeletal systems make up the human body. Minimum units, neighbourhoods, districts united by a road and green system within a geographical skeleton form the city".[1] The plan declared that the southern part of Quito would host "worker housing" as part of an industrial zone and considered these areas as urban limits.

From its initial conception, regulatory planning's functional response manifests a very evident segregation of ideologies when deciding where to locate residential areas. This phenomenon was later translated into area coding in a 1967 plan, and a neutral stance was adopted with regard to segregation that achieved normative sectorisation and separated sections of the city as isolated elements.

Santa Anita development began in 1970 and was located in the southern peripheral area of Quito. The project aligned with Jones Odriozola's plan since the selection of lands were zoned for social housing. However, these were lands where specific dynamics or processes of urbanisation did not yet exist, and the only nearby feature at the time of the project's development was a military facility with a single access road. A significant-scale housing complex was projected and built in an area where the city had not yet "arrived."

In terms of connectivity with the existing urban layout at the time of the planning of the complex, the necessary articulation roads were not constructed, leaving the four built blocks as isolated elements of the urban structure.

In the 1970s, there was a large-scale architectural and urban development that left certain areas of the city "incomplete." While Jones Odriozola's plan established certain peripheral areas for the development of social housing, promoters prioritised low land costs in distant areas over the benefits of inserting collective housing in non-peripheral land; such experiences were replicated. Social housing did not fulfil its purpose and caused significant disruptions in the growth of the city due to several processes of land speculation.

In terms of state production of social housing, processes mainly fall on the Ecuadorian Housing Bank and the Social Security Institute. It was evident that the selection of areas in the southern part of the city was prioritized.

Santa Anita presents itself as a social housing complex that, from its initial conception prioritises the hierarchical arrangement of the ensemble

over the individual housing units. Jones Odriozola establishes the functional relationships of the different elements in the city with a scalar consideration; relevant developments in architecture constitute "minimum neighbourhood units." These elements, according to their growth, made up neighbourhoods, small districts, and large districts. The initial plan for Santa Anita which considered a development of 4000 houses was a crucial component of this arrangement.

The single-family homes are arranged in a perimeter building creating distinct blocks with each house constituting an independent plot. The grouping of houses occurs around a central space, which is accessible by pedestrian streets, all with public nature. The interior of each block is used for communal recreational spaces and pedestrian circulation. The private entrances of the houses are oriented both towards vehicular circulation streets and towards public pedestrian streets. Public space is given necessary relevance from the configuration of residential elements for community life.

From an architectural standpoint, there is very meticulous spatial work in terms of transitions between public and private spaces. Within a small space, small elements served as transitions that allow the user to experience the change from the public realm of the street and sidewalks to the private area with a front garden, small changes of level, the house entrances, and a low-impact corner treatment.

4. DISSOLVING POLARITIES THROUGH THE BLOCK

The establishment of the Ecuadorian Housing Bank (1961)[2] and subsequently the National Housing Board (1973) led to the development of the various housing complexes in the late 1960s. This had two fundamental consequences: firstly, the emergence of a new collective form of habitation; and secondly, an interest from architects in social housing. Modern architectural concepts began to be applied to the most disadvantaged socioeconomic strata.

The project is designed to separate pedestrian and vehicular traffic. In fact, vehicular flows surround groupings of pairs of blocks peripherally, privileging the pedestrian character of the block interiors. The only vehicular space within the blocks is parking space that function as "*pockets*" within them. By applying this concept and arranging compact housing around open communal spaces, a pedestrian-friendly grouping with a human scale is achieved, using the characteristic orthogonal fabric of Modern urbanism. In this way, a system of pedestrian streets is created, connecting through the association of blocks, forming a complex network of horizontal pedestrian paths that establish a gradation between domestic and urban scales.

The interior passages have a public character, which creates a sense of similarity between the exterior and interior dwellings. There is no typological distinction between the dwellings oriented towards the external streets and those oriented towards the internal passages and block centres. The architectural design responds equally to both pathways, despite their different conditions.

The bridge-house serves as a residential threshold, reducing the scale of the interior passages and encouraging a collective understanding rather

than a public one. Therefore, it acts as a transition between the different vehicular hierarchies.

The project operates through a system of layers that articulate the public, the collective, and the private. These layers are materialised in an outer band attached to the main facade of the houses, which functions as a garden. This element provides the private domestic space with its own exterior that is directly related to the communal areas, in what could be termed an attempt to reclaim traditional gathering spaces.[3] This space ensures an adequate distance between blocks (6 metres) to guarantee proper sunlight exposure and humanisation of the urban space. While the interior pedestrian streets are 2 metres wide, the gardens ensure spatial relief between dwellings.

The concept of domesticity is defined by a scalar rather than a functional question, and the relationship between the public and the private does not occur as opposition but progressively, with the collective serving as an intermediary. The typological choice of the project establishes a dialogue between the scale of the house and that of the block.

The individual condition of the house, reinforced by the constructive joints and other elements such as the eaves that distinguish entrances, is counteracted by the geometric grouping, and the use of a homogeneous language that achieves a cohesive association of elements without resorting to typological models of a larger scale and compactness such as the slab, which is the archetypal model of Modern collective housing. Through a multiscale approach, the project effectively balances the individuality of residential units and the notion of the block ensemble.

It is noteworthy that while the modern project proposed orthogonal blocks as an archetype (rationalist grid), this is also found in previous traditional urban models and the foundational urban fabric of the vast majority of Latin American cities, which does not go overlooked by Germán Samper. In this sense, a conceptual hybridisation can be perceived between modern ideals (in the most orthodox sense inherited from the CIAM) and the traditional.[4]

The project blends modern ideas and inheritances. This is evident in elements such as the formal language or the use of the orthogonal grid, which reflect ideas from the CIAM. These include the integration between architecture and urbanism, between house and city, with the block serving as an articulating element from both a morphological and conceptual perspective.

Residential architecture defines collective spaces seeking a new and more human scale. Housing, collective space, and public space form an indissoluble system in which the unit of aggregation is not the house but the block.

> *[...] In my opinion, the current architecture is detached from the urban phenomenon, as the notion of a proper urban ensemble is something more than an agglomeration of isolated and disparate elements [...]*[5]

The project in Santa Anita is characterised by an urban rather than architectural structure that acts as an efficient assembly capable of adapting. Through this model, which serves as the basic unit of aggregation, the Santa Anita project

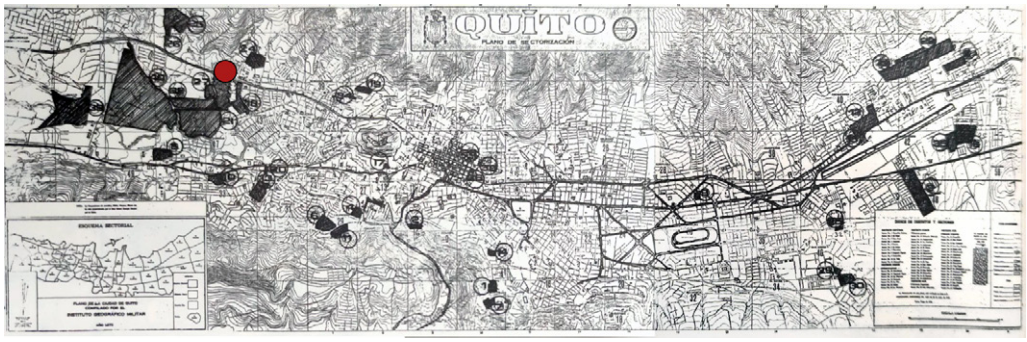
positions itself between the domestic and the urban, between the public and the private, between the individual and the collective, between Modern orthodoxy and post-CIAM reaction, dissolving conceptual polarisation.

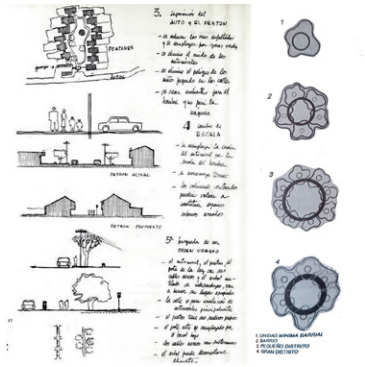
5. BETWEEN JONES ODRIOZOLA'S CELL AND SAMPER & BANDERAS'S BLOCK

The reference to the European Modern Movement transformed certain buildings into by-products of cultural consumption with an aspirational quality widely embraced in Quito. In the pursuit of progress, the state of the image is fundamental; these references influenced the image, although not necessarily progress.

The spatial characteristics of the project encourages social connections, leading to the formation of a neighbourhood association responsible for certain aspects such as the maintenance of interior gardens or self-management of security. However, the lack of regulations protecting the project creates the potential for changes to its layout, such as increasing the number of stories in houses beyond current limits, allowing commercial uses on the street-facing sides of houses, and the absence of a public body responsible for preserving modern heritage (as opposed to colonial heritage).



The autonomy of the lots in terms of property allows for individual decisions that can modify the original condition, regardless of the criteria of the neighbourhood association without legal attribution. The current state of the project is fundamentally a consequence of deregulation and normative lack of protection, and not attributable to the architectural approach of the project *per se*.



As in other Latin American contexts, this residential exploration reveals the administrative contradictions of an architectural project more advanced than its regulatory context.

The urban proposal and the residential complex stem from the additive logic inherited from modern principles. However, they differ in the scalar approach manifested in the divergence of the understanding of the basic grouping module. Jones Odriozola emphasises the "*minimum neighbourhood units*," while Samper, focuses on the block. The scale proposed by Samper and Banderas implies a humanisation of urban space linking it to the domestic scale. On the other hand, Jones Odriozola's vision applies the principles inherited from the "*Charter of Athens*" more literally, and Samper and Banderas's approach considers the contributions and reflections of subsequent decades stemming from debates arising from the CIAM principles.

The alteration of Santa Anita, compared to the original planning, occurred from the outset.[6] The current state of the complex shows that out of the initial 200 housing units, less than 10% maintain their original configuration. The regulations allow for both minor aesthetic modifications and significant morphological, typological, and functional changes due to the cadastral independence of the properties. The neighbours have subcategorised the streets and public spaces on a gradual scale to increase privacy from the heart of the block outwards, dividing it into

6. *"When they were being built, I […] attended once after they were completed and saw that they had already begun, as is typical in these social housing developments, the misguided intervention of the people."* Fausto Banderas, "Santa Anita residential complex and the experience with Germán Samper: interview with Fausto Banderas," by Néstor Llorca, Verónica Vaca and Enrique Ferreras, April 2024.

two independent realities, one towards the interior fostering a sense of community, and another towards the exterior in which the buildings function in isolation.

The project gravitates in a constant state of tension between the "neighbourhood cell" derived from Jones Odriozola's proposal in urban planning and the grouping based on the block by Samper and Banderas. Despite the multiple individual modifications on the different housing units, the notion of an ensemble based on the block configuration prevails in the project. ■

BIOGRAPHY

Verónica Vaca Proaño. Architect (UCE,2012). Master of Urban Design at The University of Melbourne (Australia, 2016). Tenure Professor at the Faculty of Architecture and Civil Engineering at “Universidad Internacional SEK” (Quito, Ecuador). Verónica has been the Academic Director of the Architecture Programme since 2020. Her teaching experience includes architectural and urban design studios as well as core subjects about theory of architecture and urbanism. She participates in research groups focusing on urban morphology, typology, and contemporary habitat. She has experience with design studios that explore alternatives that are context specific. Her professional experience is dedicated to urban and architectural design and construction.

Néstor Llorca Vega. Architect (PUCE,2008). Master in Advanced Project in Architecture and City (UAH, 2010), PhD Cum Laude in Architecture with the research *“Arquitecturas híbridas de culturas híbridas, el caso de Quito en el siglo XX”* (UAH,2022). He is a prolific author and speaker, notably presenting at Docomomo-2022 and co-organising SAL17. Member of research groups on contemporary habitat, intelligent environments and *Pioneras de la Arquitectura Ecuatoriana*, a book with which he won the publication award at the Quito Architecture Biennial 2022. Dean of the Faculty of Architecture at SEK International University (2017-2022). He balances academic duties with architectural projects at I+D+A.

Enrique Ferreras Cid. Architect, M.Arch from the University of Valladolid. PhD candidate in Architecture at the University of Alcalá de Henares, developing research on open collective residence systems. He has been a professor at the University of the Americas (2015-2016) and is currently a tenured professor at SEK International University (2016-present) in the areas of project, history, and architectural theory. He has published indexed articles, as well as various book chapters both individually and as co-authors focused on the areas of Theory, Project, and Architectural Criticism. He works as a designer and is currently co-founder of the architecture studio M+E.
